Received 20 October 2010; final version received 1 March 2012; accepted 24 July 2012

Abstract

We analyze the preference aggregation problem without the assumption that individuals and society have fully determined and observable preferences. More precisely, we endow individuals and society with sets of possible von Neumann–Morgenstern utility functions over lotteries. We generalize the classical Pareto and Independence of Irrelevant Alternatives axioms and show they imply a generalization of the classical neutrality assumption. We then characterize the class of neutral social welfare functions. This class is considerably broader for indeterminate than for determinate utilities, where it basically reduces to utilitarianism. We finally characterize several classes of neutral social welfare functions for indeterminate utilities, including the utilitarian and “multi-utilitarian” classes.

1. Introduction

A common feature of social choice theory is the assumption that individual have completely determined preferences or utilities, that are fully identified by the social planner. Such an assumption might, however, seem very demanding. First, individuals may envision more than one utility function, either because their preferences are incomplete (Aumann [2], Bewley [3], Dubra et al. [11], Evren and Ok [12]), or because they are uncertain about their tastes (Cerreia-Vioglio [5], Dekel et al. [10], Koopmans [15], Kreps [16]), or because they are driven by several “selves” or “rationales” (Ambrus and Rozen [1], Green and Hojman [13], Kalai et al. [14], May [17]). Second, even if all individuals have single, fully determined utility functions, fully identifying them may be either infeasible or too costly, so that the social planner may be unable or unwilling to assign a precise utility function to each individual (C. Manski [6,7]).

This paper proposes a first step towards a social choice theory allowing for situations in which individuals have only partially determined preferences or utilities. In order to account for such situations, we endow individuals with sets of utility functions. Such a set represents the possible utility functions the individual may have, according to the social planner. The particular case where this set is a singleton then corresponds to the standard setting in which the individual has a single, fully determined utility function. We shall say that the utility function is *determinate* in this case and *indeterminate* otherwise, to summarize the different situations mentioned above.

We consider risky alternatives and study social welfare functions mapping profiles of individual von Neumann–Morgenstern (henceforth vNM) utility sets to social vNM utility sets. In this setting, when utility functions are determinate, classical Pareto and Independence of Irrelevant Alternatives axioms lead to a very specific and tractable form of the social welfare function: utilitarianism (Coulhon and Mongin [8]). Specifically, the Pareto and Independence of Irrelevant Alternatives axioms together yield a classical neutrality property: the social utility level is a function of the individual utility levels only. Linearity of the vNM utility function then straightforwardly implies linearity of the social utility level in the individual utility levels. Hence, the social utility function is a linear combination of the individual utility functions.

As it turns out, moving from determinate to indeterminate utilities makes things much more complex even in this simple setting. First, in general, there is not a single utility level, but a set (in fact, an interval) of possible utility levels for each alternative, so that the classical neutrality property cannot be used. Natural generalizations of the Pareto and Independence of Irrelevant Alternatives axioms nevertheless yield a generalized “interval-neutrality” property: the social utility interval is a function of the individual utility intervals only. Second, linearity of vNM utility functions does not imply any linearity property for utility intervals. It however yields weaker convexity properties which, together with other regularity properties, allow us to express the social utility interval as a union of linear combinations of individual utility intervals. Third, pinning down the utility intervals for all alternatives is not enough to fully pin down the social utility set. Despite this, the generalized axioms are powerful enough to yield full-fledged characterization results.

The remainder of the paper is built as follows. Section 2 describes the setup and the generalized Pareto and Independence of Irrelevant Alternatives axioms. In Section 3 the interval-neutrality property is defined and shown to be implied by the Pareto and Independence of Irrelevant Alternatives axioms, and a characterization of interval-neutral social welfare functions is provided. This characterization of interval neutrality, although falling short of fully pinning down the social utility set, is the key technical step towards full-fledged characterization results, which are obtained in Section 4. In particular, the classes of utilitarian and “multi-utilitarian”

social welfare functions are characterized, and their degree of “social indeterminacy” is analyzed. Section 5 provides generalizations of the preceding results to more general alternatives and domains. Section 6 concludes. Proofs are gathered in Appendix A.

2. Setup

Let X be a non-empty set of social alternatives. We assume that X is a set of probability measures (lotteries) over a non-empty set Z of social (sure) outcomes and that, furthermore, X is convex and contains all probability measures on Z with finite support (simple lotteries). Thus we may for instance take X to be the set of all probability measures on Z with finite, countable, or (if a topology on Z is given) compact support. We will maintain this assumption on X until Section 5, in which we will consider more general sets of alternatives. Given two alternatives $x, y \in X$ and a number $\lambda \in [0, 1]$, we let $x\lambda y$ denote the convex combination $\lambda x + (1 - \lambda)y \in X$.

A utility function u on X associates to each alternative $x \in X$ a utility level $u(x) \in \mathbb{R}$. A utility function u on X is a vNM utility function if it is affine, i.e. if $u(x\lambda y) = \lambda u(x) + (1 - \lambda)u(y)$ for all $x, y \in X$ and all $\lambda \in [0, 1]$. Let $P \subseteq \mathbb{R}^X$ denote the set of all vNM utility functions on X . P is a linear subspace of \mathbb{R}^X and contains all constant functions. Given a real number $\gamma \in \mathbb{R}$, we abuse notation by also letting γ denote the corresponding constant function in P .

We consider non-empty sets of utility functions, i.e. non-empty subsets of \mathbb{R}^X . Our interpretation of such a set is that the utility function may possibly be any member of the set, without further information being available. The utility function is *determinate* if the set is a singleton and *indeterminate* otherwise. We restrict attention to sets of vNM utility functions. More precisely, let \mathcal{P} denote the set of all non-empty, compact, and convex subsets of P , where P is endowed with the subspace topology and \mathbb{R}^X with the product topology. Note that \mathcal{P} contains in particular all convex hulls of finite sets of vNM utility functions on X and, hence, all singletons.

A vNM utility set $U \in \mathcal{P}$ can be seen as representing an underlying preference relation \succsim over alternatives in X , in the sense that for all $x, y \in X$,

$$x \succsim y \Leftrightarrow [\forall u \in U, u(x) \geq u(y)]. \quad (1)$$

The special case where U is a singleton then corresponds to standard expected utility preferences (von Neumann and Morgenstern [19]). When U is not a singleton, on the other hand, the preference relation \succsim is incomplete, i.e. there are alternatives $x, y \in X$ such that neither $x \succsim y$ nor $y \succsim x$ (unless all elements of U are positive affine transformations of one another), but satisfies all the other standard vNM axioms. Shapley and Baucells [23] axiomatize the existence of a closed and convex subset U of P satisfying (1), whereas Dubra et al. [11], assuming X is the set of all Borel probability measures on a compact metric space Z , axiomatize the existence of a closed and convex set U of continuous functions in P satisfying (1).¹

Let I be a non-empty and finite set of individuals. Given a non-empty domain $\mathcal{D} \subseteq \mathcal{P}^I$, a social welfare function F on \mathcal{D} associates to each profile $(U_i)_{i \in I} \in \mathcal{D}$ of individual (vNM)

¹ Neither of these two results fully characterize the existence of a utility set $U \in \mathcal{P}$ satisfying (1). Indeed, the set U in the former result cannot be taken to be compact in general. However, a sufficient condition for the existence of a compact U is that all functions in U be bounded (since we can then scale all these functions down to range within a given bounded interval and then take the closure of the convex hull of these scaled functions), and this sufficient condition will obtain in particular if either Z is finite or X contains all probability measures on Z with countable support. The set U in the latter result, on the other hand, can always be taken to be compact (because all utility functions in this set are necessarily bounded), but the additional continuity property rules out some members of \mathcal{P} , unless Z is finite.

utility sets a social (vNM) utility set $U = F((U_i)_{i \in I}) \in \mathcal{P}$. We will maintain the assumption that $\mathcal{D} = \mathcal{P}^I$ from now on, and will relax it in Section 5.

The most classical axioms for social welfare functions with determinate utilities are the Pareto and Independence of Irrelevant Alternatives axioms. Both of them can be generalized to indeterminate utilities. The Pareto Indifference (resp. Pareto Weak Preference) axiom requires that if all individuals are indifferent between alternatives x and y (resp. weakly prefer x to y) then so does society. To the extent that a utility set $U \in \mathcal{P}$ can be seen as representing an underlying preference relation in the sense of (1), it is natural to generalize the Pareto axioms to utility sets as follows.

Axiom 1 (Pareto Indifference). For all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x, y \in X$, if $u_i(x) = u_i(y)$ for all $u_i \in U_i$ and all $i \in I$ then $u(x) = u(y)$ for all $u \in F((U_i)_{i \in I})$.

Axiom 2 (Pareto Weak Preference). For all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x, y \in X$, if $u_i(x) \geq u_i(y)$ for all $u_i \in U_i$ and all $i \in I$ then $u(x) \geq u(y)$ for all $u \in F((U_i)_{i \in I})$.

Independence of Irrelevant Alternatives essentially requires the social ranking between alternatives x and y to depend only on the individual rankings between x and y . Again, to the extent that a utility set $U \in \mathcal{P}$ can be seen as representing an underlying preference relation in the sense of (1), it is natural to view the ranking between x and y as determined by the set $\{(u(x), u(y)) : u \in U\}$. Let us introduce the following notation: given a subset Y of X and a utility set $U \in \mathcal{P}$, let $U|_Y$ denote the restriction of U to Y , i.e. $U|_Y = \{u|_Y : u \in U\}$.² We thus generalize the Independence of Irrelevant Alternatives axiom to utility sets as follows.

Axiom 3 (Independence of Irrelevant Alternatives). For all $(U_i)_{i \in I}, (U'_i)_{i \in I} \in \mathcal{D}$ and all $x, y \in X$, if $U_i|_{\{x,y\}} = U'_i|_{\{x,y\}}$ for all $i \in I$ then $F((U_i)_{i \in I})|_{\{x,y\}} = F((U'_i)_{i \in I})|_{\{x,y\}}$.

For a social welfare function with determinate utilities, Independence of Irrelevant Alternatives implies that the restriction of the social utility function to any finite subset of alternatives depends only on the restrictions of the individual utility functions to this subset of alternatives (Blau [4], D'Aspremont and Gevers [9]). This is simply because any function is fully determined by its restrictions to all pairs of elements of its domain. This argument does not hold for indeterminate utilities: a set of functions on a common domain is generally not fully determined by the corresponding sets of restrictions to all pairs of elements of the domain, because there is generally more than one way of “gluing” together these sets of restrictions. Nevertheless, because we restrict attention to vNM utility functions, it can in fact be shown that Independence of Irrelevant Alternatives still implies that the restriction of the social utility set to any finite subset of alternatives depends only on the restrictions of the individual utility sets to this subset of alternatives in our setting (see Lemma 15 in Appendix A).

3. Interval neutrality

In the classical Arrovian framework, neutrality refers to the fact that if alternatives x and y are ranked by individuals in a given situation (i.e. for a given profile of individual preferences)

² Given a function f on a set S and a subset T of S , $f|_T$ denotes the function on T defined by $f|_T(s) = f(s)$ for all $s \in T$.

exactly as alternatives z and w are in another situation, then the social ranking between x and y in the first situation is the same as the social ranking between z and w in the second one. In the richer framework of social welfare functions with determinate utilities, neutrality means that if the individual utility levels of alternatives x and y in a given situation are the same as the individual utility levels of alternatives z and w in another situation, then the social ranking between x and y in the first situation is the same as the social ranking between z and w in the second one (Sen [22]). If profiles of individual utility functions are mapped to social utility functions rather than social preference relations, then neutrality can be simply stated by requiring that if the individual utility levels of alternative x in a given situation are the same as the individual utility levels of alternative y in another situation, then the social utility level of x in the first situation is the same as the social utility level of y in the second situation (Coulhon and Mongin [8]).

When the utility function is indeterminate, however, an alternative does not in general have a single utility level but rather a set (in fact, a non-empty and compact interval) of possible utility levels. More precisely, given a utility set $U \in \mathcal{P}$, let $U(x) = U|_{\{x\}}$ denote the *utility interval* of an alternative $x \in X$. We generalize the neutrality property by requiring that if the individual utility intervals of alternative x in a given situation are the same as the individual utility intervals of alternative y in another situation, then the social utility interval of x in the first situation is the same as the social utility interval of y in the second situation.

Definition 1 (*Interval-neutrality*). A social welfare function F on a domain $\mathcal{D} \subseteq \mathcal{P}^I$ is *interval-neutral* if for all $(U_i)_{i \in I}, (U'_i)_{i \in I} \in \mathcal{D}$ and all $x, y \in X$, if $U_i(x) = U'_i(y)$ for all $i \in I$ then $F((U_i)_{i \in I})(x) = F((U'_i)_{i \in I})(y)$.

For determinate utilities, neutrality is equivalent to the conjunction of Independence of Irrelevant Alternatives and Pareto Indifference. This equivalence does not hold in our framework, but, it is still the case that Independence of Irrelevant Alternatives and Pareto Indifference together imply interval-neutrality.

Lemma 1. *If a social welfare function F on $\mathcal{D} = \mathcal{P}^I$ satisfies Independence of Irrelevant Alternatives and Pareto Indifference then F is interval-neutral.*

To show that the converse of Lemma 1 does not hold, let $Z = \{z_1, z_2, z_3\}$, let X be the set of all probability measures on Z , and define the social welfare function F on $\mathcal{D} = \mathcal{P}^I$ by for all $(U_i)_{i \in I} \in \mathcal{D}$, $F((U_i)_{i \in I}) = \sum_{i \in I} U_i$ if there exist $i \in I$, $u_i \in U_i$ and $z, z' \in Z$ such that $u_i(z) \neq u_i(z')$ and $F((U_i)_{i \in I}) = \{u \in P: \forall x \in X, u(x) \in \sum_{i \in I} U_i(x)\}$ otherwise. Then $F((U_i)_{i \in I})(x) = \sum_{i \in I} U_i(x)$ for all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x \in X$, so F is interval-neutral. Now, let $U = \text{conv}(\{0, 1\}) \in \mathcal{P}$ and $U' = \text{conv}(\{0, u'\}) \in \mathcal{P}$, where $u' \in P$ is defined by $u'(z_1) = u'(z_2) = 1$ and $u'(z_3) = 0$. Then $F((U_i)_{i \in I})|_{\{z_1, z_2\}} = [0, 1]^2$, so F does not satisfy Pareto Indifference. Moreover, $U'|_{\{z_1, z_2\}} = U|_{\{z_1, z_2\}}$ and $F((U'_i)_{i \in I})|_{\{z_1, z_2\}} = \text{conv}(\{(0, 0), (1, 1)\}) \neq F((U_i)_{i \in I})|_{\{z_1, z_2\}}$, so F does not satisfy Independence of Irrelevant Alternatives either.

For determinate utilities, neutrality plays a key role by carrying linearity of vNM utility functions into linearity of the social welfare function. For indeterminate utilities this is no longer the case, because vNM utility intervals do not enjoy the linearity property that vNM utility levels do. But vNM utility intervals still exhibit some (weaker) structure and, in particular, convexity properties.

Fig. 1. Example of set of utility functions.

Lemma 2.

- (a) For all $U \in \mathcal{P}$, $x, y \in X$, and $\lambda \in [0, 1]$, $U(x\lambda y) \subseteq \lambda U(x) + (1 - \lambda)U(y)$.
- (b) For all $U \in \mathcal{P}$, $x, y \in X$, and $\lambda \in [0, 1]$, $\lambda \max U(x) + (1 - \lambda) \min U(y) \in U(x\lambda y)$.

To illustrate Lemma 2, consider the example represented in Fig. 1. The set of outcomes is $Z = \{z_1, z_2\}$ and the set X of alternatives is the set of all probability measures on Z . The table on the left-hand side defines four utility functions $u_1, u_2, u_3, u_4 \in P$. These utility functions are depicted on the right-hand side graph, in which the thick horizontal segment represents X and the utility level of each alternative $x \in X$ is measured along the corresponding vertical axis. The set $U = \text{conv}(\{u_1, u_2, u_3\})$ of utility functions (i.e. all convex combinations of u_1, u_2 , and u_3) fills the shaded area on the graph.³ The utility interval $U(x)$ of an alternative $x \in X$ corresponds to the intersection of the corresponding vertical axis with this shaded area.

Lemma 2(a) states that although affinity of vNM utility functions does not extend to utility intervals, in the sense that one would have $U(x\lambda y) = \lambda U(x) + (1 - \lambda)U(y)$, an inclusion relation nevertheless holds. Equivalently, the function $x \mapsto \max U(x)$ is convex and the function $x \mapsto \min U(x)$ is concave. Lemma 2(b) states that although the shaded area on the graph is not convex, it still contains all line segments joining the maximum of a utility interval with the minimum of another utility interval, i.e. $\lambda \max U(x) + (1 - \lambda) \min U(y) \in U(x\lambda y)$. This establishes a relationship between the two functions just defined.

Armed with this lemma, we obtain the following characterization of interval-neutrality.

Theorem 1. Assume Z contains at least two elements. Then a social welfare function F on $\mathcal{D} = \mathcal{P}^I$ is interval-neutral if and only if there exists a non-empty, compact, and convex set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ such that, for all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x \in X$,

$$F((U_i)_{i \in I})(x) = \bigcup_{(\alpha, \beta, \gamma) \in \Phi} \left(\sum_{i \in I} \alpha_i U_i(x) - \sum_{i \in I} \beta_i U_i(x) + \gamma \right). \tag{2}$$

Moreover, Φ can be taken such that (2) holds for some non-empty, compact, and convex set $\Phi' \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ if and only if $\Phi \subseteq \Phi' \subseteq \{(\alpha - \eta, \beta - \eta, \gamma) : (\alpha, \beta, \gamma) \in \Phi, \eta \in \mathbb{R}_+^I\}$.

³ Given a set S , $\text{conv}(S)$ denotes the convex hull of S .

Thus a social welfare function F is interval-neutral if and only if the social utility interval is the union of a set of affine transformations of all individual utility intervals, with individual i 's utility interval entering twice in each affine transformation, once with a non-negative coefficient α_i and once with a non-positive coefficient $-\beta_i$. Moreover, the set Φ of weight-constant vectors (α, β, γ) is "almost" unique in the sense that, first, there exists a unique Φ that is minimal with respect to set inclusion and, second, another set Φ' satisfies (2) if and only if it consists in the minimal Φ to which are added weight-constant vectors that are always irrelevant to the social utility interval. Indeed, it is easily checked that, for all utility interval $U_i(x)$, if $\alpha_i \geq \alpha_i - \eta_i \geq 0$ and $\beta_i \geq \beta_i - \eta_i \geq 0$ then $(\alpha_i - \eta_i)U_i(x) - (\beta_i - \eta_i)U_i(x) \subseteq \alpha_i U_i(x) - \beta_i U_i(x)$.

It is interesting to compare the characterization (2) of interval-neutrality we obtain for indeterminate utilities with a set-valued version of the characterization of neutrality obtained by Couhlon and Mongin [8] for determinate utilities, namely:

$$F((U_i)_{i \in I}) = \sum_{i \in I} \theta_i U_i + \gamma, \tag{3}$$

for some $\theta \in \mathbb{R}^I$ and $\gamma \in \mathbb{R}$. There are three dimensions along which (2) is more general than (3):

- (i) In (2) the social utility interval is made of several affine combinations of all individual utility intervals, rather than a single one as in (3).
- (ii) In (2) each individual i 's utility interval enters twice in each affine transformation rather than once (so (3) corresponds to the particular case where either $\alpha_i = 0$ or $\beta_i = 0$). To illustrate this point, let $I = \{1, 2\}$ and consider the two social welfare functions $F_1(U_1, U_2) = U_1 + U_2$ and $F_2(U_1, U_2) = 2(U_1 + U_2) - (U_1 + U_2)$, which obviously satisfy (2). F_1 uses only one weight per individual whereas F_2 uses two. These two functions agree if both $U_1(x)$ and $U_2(x)$ are singletons, but otherwise F_1 yields a smaller utility interval than F_2 . For instance, $F_1([0, 1], [0, 1]) = [0, 2] \subset [-2, 4] = F_2([0, 1], [0, 1])$. More generally, for any social welfare function F satisfying (2), we have

$$\begin{aligned} F((U_i)_{i \in I})(x) &= \bigcup_{(\alpha, \beta, \gamma) \in \Phi} \left\{ \sum_{i \in I} (\alpha_i u_i(x) - \beta_i v_i(x)) + \gamma : u_i, v_i \in U_i, i \in I \right\} \\ &\supseteq \bigcup_{(\alpha, \beta, \gamma) \in \Phi} \left\{ \sum_{i \in I} (\alpha_i - \beta_i) u_i(x) + \gamma : u_i \in U_i, i \in I \right\} \\ &= \bigcup_{(\alpha, \beta, \gamma) \in \Phi} \left(\sum_{i \in I} (\alpha_i - \beta_i) U_i(x) + \gamma \right), \end{aligned}$$

where, in general, equality holds if and only if $U_i(x)$ is a singleton for all $i \in I$.

- (iii) Whereas (3) fully pins down the social set of utility functions, (2) only pins down all social utility intervals. To illustrate why a utility set is not fully pinned down by all its utility intervals in general, let us go back to the example depicted in Fig. 1, and note that the set $U' = \text{conv}(\{u_1, u_2, u_3, u_4\})$ of utility functions fills the same shaded area on the graph as U does, so that we have $U'(x) = U(x)$ for all $x \in X$, although we clearly have $U' \neq U$ since $u_4 \notin U$. This is because U and U' only differ in terms of "utility correlations": in both sets of utility functions it is possible that the utility level of z_1 be equal to 4 and it is also possible that the utility level of z_2 be equal to 1, but in U' these two possibilities may arise from the same utility function whereas in U they cannot.

Finally, let us briefly sketch the proof of the “only if” part of [Theorem 1](#) (the “if” part is straightforward). First note that, from interval-neutrality, we know that $F((U_i)_{i \in I})(x)$ is a function of $(U_i(x))_{i \in I}$. Equivalently, both $\max F((U_i)_{i \in I})(x)$ and $\min F((U_i)_{i \in I})(x)$ are functions of $(\max U_i(x), \min U_i(x))_{i \in I}$. Now, these two functions are not necessarily affine but [Lemma 2](#) does impose some structure on them. Most importantly, $\max F((U_i)_{i \in I})(x)$ is convex, non-decreasing in each $\max U_i(x)$, and non-increasing in each $\min U_i(x)$, whereas $\min F((U_i)_{i \in I})(x)$ is concave, non-decreasing in each $\min U_i(x)$, and non-increasing in each $\max U_i(x)$. These two functions are also Lipschitzian and (up to a change of variable) share the same recession function. These properties enable us to construct, using standard results on conjugate convex functions, a common, compact set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ such that

$$\begin{aligned} \max F((U_i)_{i \in I})(x) &= \max_{(\alpha, \beta, \gamma) \in \Phi} \left(\sum_{i \in I} \alpha_i \max U_i(x) - \sum_{i \in I} \beta_i \min U_i(x) + \gamma \right), \\ \min F((U_i)_{i \in I})(x) &= \min_{(\alpha, \beta, \gamma) \in \Phi} \left(\sum_{i \in I} \alpha_i \min U_i(x) - \sum_{i \in I} \beta_i \max U_i(x) + \gamma \right), \end{aligned}$$

which is equivalent to [\(2\)](#).

4. Utilitarianism

As we have seen, [Theorem 1](#) falls short of fully pinning down the social utility set (and hence, social preferences) because, roughly speaking, utility intervals do not keep track of “utility correlations” between alternatives. Unlike interval-neutrality, Independence of Irrelevant Alternatives and Pareto Indifference both impose some structure on these correlations. This structure turns out to be sufficient to obtain a full-fledged characterization of social welfare functions satisfying these two axioms.

Theorem 2. *Assume Z contains at least three elements. Then a social welfare function F on $\mathcal{D} = \mathcal{D}^I$ satisfies Independence of Irrelevant Alternatives and Pareto Indifference if and only if there exists a non-empty, compact, and convex set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ such that, for all $(U_i)_{i \in I} \in \mathcal{D}$,*

$$F((U_i)_{i \in I}) = \bigcup_{(\alpha, \beta, \gamma) \in \Phi} \left(\sum_{i \in I} \alpha_i U_i - \sum_{i \in I} \beta_i U_i + \gamma \right). \tag{4}$$

Moreover, Φ can be taken such that [\(2\)](#) holds for some non-empty, compact, and convex set $\Phi' \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ if and only if $\Phi \subseteq \Phi' \subseteq \{(\alpha - \eta, \beta - \eta, \gamma) : (\alpha, \beta, \gamma) \in \Phi, \eta \in \mathbb{R}_+^I\}$.

Unlike the characterization [\(2\)](#) of interval-neutral social welfare functions, [\(4\)](#) fully pins down the social utility set and not only the utility intervals. Compared with the characterization [\(3\)](#) obtained by [Coulhon and Mongin \[8\]](#) for determinate utilities, [\(4\)](#) remains more general in the dimensions (i) and (ii) described above.

Regarding dimension (i), let us recall that in [\(3\)](#) where each individual is assigned one (positive, negative, or null) weight, strengthening Pareto Indifference to Pareto Weak Preference ensures that all weights are non-negative, thereby making the social welfare function *utilitarian*.⁴ Similarly, in [\(4\)](#) where each individual is assigned one non-negative and one non-positive

⁴ We call utilitarian any social welfare function in which social utility is a non-negative affine combination of individual utilities, even if individuals do not have equal weights.

weight, Pareto Weak Preference ensures that all non-positive weights are equal to zero, so we obtain the following characterization.

Corollary 1. Assume Z contains at least three elements. A social welfare function F on $\mathcal{D} = \mathcal{D}^I$ satisfies Independence of Irrelevant Alternatives and Pareto Weak Preference if and only if there exists a non-empty, compact, and convex set $\Omega \subset \mathbb{R}_+^I \times \mathbb{R}$ such that, for all $(U_i)_{i \in I} \in \mathcal{D}$,

$$F((U_i)_{i \in I}) = \bigcup_{(\theta, \gamma) \in \Omega} \left(\sum_{i \in I} \theta_i U_i + \gamma \right). \tag{5}$$

Moreover, Ω is unique.

Such social welfare functions may be called *multi-utilitarian*, as they are unions of utilitarian rules. Each individual is thus assigned a set of weights rather than a single one (note that this makes the set of weight-constant vectors fully unique). Utilitarian social welfare functions then correspond to the particular case in which the set of weight-constant vectors is a singleton. To characterize them we introduce the following axiom.

Axiom 4 (Determinacy Preservation). For all $(\{u_i\})_{i \in I} \in \mathcal{D}$, there exists $u \in P$ such that $F((\{u_i\})_{i \in I}) = \{u\}$.

Determinacy Preservation simply requires social utility to be determinate whenever individual utilities are. We obtain the following characterization of utilitarianism for utility sets.

Corollary 2. Assume Z contains at least three elements. A social welfare function F on $\mathcal{D} = \mathcal{D}^I$ satisfies Independence of Irrelevant Alternatives, Pareto Weak Preference, and Determinacy Preservation if and only if there exist a vector $\theta \in \mathbb{R}_+^I$ and a number $\gamma \in \mathbb{R}$ such that, for all $(U_i)_{i \in I} \in \mathcal{D}$,

$$F((U_i)_{i \in I}) = \sum_{i \in I} \theta_i U_i + \gamma. \tag{6}$$

Moreover, θ and γ are unique.

Note that social welfare functions satisfying (4) (and, hence, those satisfying (5) or (6)) enjoy the following properties:

- (i) For all $(U_i)_{i \in I}, (U'_i)_{i \in I} \in \mathcal{D}$, if there exist a strictly positive real number a and a collection $(b_i)_{i \in I}$ of real numbers such that $U'_i = aU_i + b_i$ for all $i \in I$ then there exists a real number b such that $F((U'_i)_{i \in I}) = aF((U_i)_{i \in I}) + b$. This invariance property, called “cardinal measurability, unit-comparability”, is already known to be satisfied by utilitarian rules in the particular case of determinate utilities (D’Aspremont and Gevers [9]).
- (ii) For all $(U_i)_{i \in I} \in \mathcal{D}$, if $F((U_i)_{i \in I})$ is a singleton then, for all $i \in I$, either U_i is a singleton or $\alpha_i = \beta_i = 0$ for all $(\alpha, \beta, \gamma) \in \Phi$. An individual $i \in I$ for which $\alpha_i = \beta_i = 0$ for all $(\alpha, \beta, \gamma) \in \Phi$ is completely “irrelevant” to society, in the sense that for all $(U_j)_{j \in I}, (U'_j)_{j \in I} \in \mathcal{D}$, $F((U_j)_{j \in I}) = F((U'_j)_{j \in I})$ whenever $U_j = U'_j$ for all $j \in I \setminus \{i\}$. Thus, if all individuals are “relevant” then social utility can only be determinate if all individual utilities are themselves determinate: society cannot “resolve” individual indeterminacy. For example, one may find it desirable for society to select two profiles $(u_i)_{i \in I}, (v_i)_{i \in I}$

Fig. 2. Example of set of utility functions (continued).

of individual utility functions out of each profile $(U_i)_{i \in I}$ of individual utility sets and use some affine transformation $\sum_{i \in I} \alpha_i u_i - \beta_i v_i + \gamma$ of the selected individual utility functions as the (determinate) social utility function, but this is incompatible with the axioms of **Theorem 2** (and, in fact, with interval-neutrality).

- (iii) For all $(U_i)_{i \in I}, (U'_i)_{i \in I} \in \mathcal{D}$, if $U_i \subseteq U'_i$ for all $i \in I$ then $F((U_i)_{i \in I}) \subseteq F((U'_i)_{i \in I})$. Thus, more indeterminacy at the individual level translates to more indeterminacy at the social level.
- (iv) $F_1((U_i)_{i \in I}) \subseteq F_2((U_i)_{i \in I})$ for all $(U_i)_{i \in I} \in \mathcal{D}$ if and only if $\Phi_1 \subseteq \Phi_2$. Thus F_1 is “socially more determinate” than F_2 if and only if F_1 has a smaller set of weight-constant vectors than F_2 . Hence, in particular, utilitarian social welfare functions are the socially most determinate social welfare functions satisfying Independence of Irrelevant Alternatives and Pareto Weak Preference.

Finally, let us briefly sketch the proof of the “only if” part of **Theorem 2** (the proof of the “if” part is straightforward). Beforehand, it is useful to understand in more detail why a set of utility functions is only partially pinned down by all utility intervals. To this end, let us go back to the example that we considered in **Fig. 1** in Section 3. The definition of the four utility functions $u_1, u_2, u_3, u_4 \in P$ on the set $Z = \{z_1, z_2\}$ is recalled in the left-hand side table of **Fig. 2**. The right-hand side graph depicts these utility functions but this time in \mathbb{R}^Z rather than \mathbb{R}^X (this is possible, of course, since a vNM utility function $u \in P$ is fully determined by the vector $(u(z_1), u(z_2)) \in \mathbb{R}^Z$). The set $U = \text{conv}(\{u_1, u_2, u_3\})$ of utility functions now corresponds to the shaded triangle $u_1 u_2 u_3$. The utility interval $U(x)$ of alternative $x \in X$ (the set X of alternatives is represented by the thick segment on the graph) can now be visualized as follows: $\max U(x)$ corresponds to the hyperplane supporting U in the (normal) direction x whereas $\min U(x)$ corresponds to the hyperplane supporting U in the direction $-x$.

Being essentially a compact and convex subset of \mathbb{R}^Z , a set of utility functions is fully determined by its supporting hyperplanes in all directions of \mathbb{R}^Z . The utility intervals of all alternatives, however, only determine these supporting hyperplanes in the non-negative and non-positive directions and, hence, do not fully pin down the set of utility functions. Thus, the set $U' = \text{conv}(\{u_1, u_2, u_3, u_4\})$ of utility functions (corresponding to the quadrilateral $u_1 u_2 u_3 u_4$), although strictly larger than U , only differs from U in directions with both positive and negative components and, hence, yields the same utility intervals as U for all alternatives.

Now for the proof sketch, first note that by [Theorem 1](#), we know there exists a non-empty, compact, and convex set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ such that (2) holds. In order to strengthen (2) to (4), it is sufficient to show that two social welfare functions F and F' on $\mathcal{D} = \mathcal{D}^I$ satisfying Independence of Irrelevant Alternatives and Pareto Indifference that always yield the same social utility interval must always yield the same social utility set. Given our topological assumptions and since we restrict attention to vNM utilities, it turns out to be sufficient to show that F and F' must always yield the same restriction of the social utility set to any pair of alternatives.

So suppose there is a profile $(U_i)_{i \in I} \in \mathcal{D}$ such that $F((U_i)_{i \in I})(x) = F'((U_i)_{i \in I})(x)$ for all $x \in X$ but $F((U_i)_{i \in I})|_{\{z_1, z_2\}} \neq F'((U_i)_{i \in I})|_{\{z_1, z_2\}}$ for two outcomes $z_1, z_2 \in Z$. As we just explained, $F((U_i)_{i \in I})|_{\{z_1, z_2\}}$ and $F'((U_i)_{i \in I})|_{\{z_1, z_2\}}$ must then differ in some direction of $\mathbb{R}^{\{z_1, z_2\}}$ with both positive and negative components. For instance, $F((U_i)_{i \in I})|_{\{z_1, z_2\}}$ and $F'((U_i)_{i \in I})|_{\{z_1, z_2\}}$, may be the sets U and U' of the previous example, which differ in the direction $(2, -1)$ (among others), as $2u_4(z_1) - u_4(z_2) > 2u(z_1) - u(z_2)$ for all $u \in U$. Take then an outcome $z_3 \in Z \setminus \{z_1, z_2\}$ and a profile $(\tilde{U}_i)_{i \in I} \in \mathcal{D}$ that agrees with $(U_i)_{i \in I}$ on $\{z_1, z_2\}$ and such that $\tilde{u}_i(z_3) = 2\tilde{u}_i(z_1) - \tilde{u}_i(z_2)$ for all $\tilde{u}_i \in \tilde{U}_i$ and all $i \in I$. By Independence of Irrelevant Alternatives, we must then have $F((\tilde{U}_i)_{i \in I})|_{\{z_1, z_2\}} = U$ and $F'((\tilde{U}_i)_{i \in I})|_{\{z_1, z_2\}} = U'$ and, by Pareto Indifference, we must also have $\tilde{u}(z_3) = 2\tilde{u}(z_1) - \tilde{u}(z_2)$ for all $\tilde{u} \in F((U_i)_{i \in I}) \cup F'((U_i)_{i \in I})$. Hence the above inequality yields $F((\tilde{U}_i)_{i \in I})(z_3) = [3, 6]$ and $7 \in F'((\tilde{U}_i)_{i \in I})(z_3)$, a contradiction.

5. General alternatives and domains

Up to now we have maintained two assumptions in order to simplify the exposition. First, the set of alternatives is a convex set of probability measures over some set Z of outcomes containing all probability measures on Z with finite support. Second, the domain of the social welfare function is the set of all profiles of (vNM) utility sets on X . Our results, however, also hold for other alternatives and domains. In this section we state general properties of the set of alternatives and the domain of the social welfare functions that are sufficient for our results and we discuss some particular settings in which these properties are satisfied.

First, we assume X is a *mixture space*, i.e. any set endowed with a mixing operation $[0, 1] \times X \times X \rightarrow X$, $(\lambda, x, y) \mapsto x\lambda y$, such that for all $x, y \in X$ and all $\lambda, \mu \in [0, 1]$, $x1y = x$, $x\lambda y = y(1 - \lambda)x$, and $(x\lambda y)\mu y = x(\lambda\mu)y$. Note that all definitions and axioms introduced so far have been stated with this general notation and, hence, apply to any mixture space.

Any convex set of probability measures over some set Z of outcomes is a mixture space, whether it contains all probability measures with finite support or not. Thus, besides all instances mentioned in [Section 2](#), convex sets of probability measures with continuous or differentiable density are also mixture spaces. A somewhat different example, that has received recent attention in the literature, is the set of all compact and convex subsets of any of the above instances of mixture spaces, interpreted as menus (opportunity sets).

More generally, whenever X is a convex subset of some linear space, defining the mixing operation $x\lambda y = \lambda x + (1 - \lambda)y$ by means of the vector addition and scalar multiplication operations turns it into a mixture space. Such a mixture space, in addition, has the particular property that any pair of $\{x, y\} \subseteq X$ of distinct alternatives is *separated*, i.e. for all $r, s \in \mathbb{R}$ there exists $u \in P$ such that $u(x) = r \neq u(y) = s$. In fact, [Mongin \[18\]](#) shows that all pairs of distinct alternatives in X are separated if and only if there exists a mixture preserving bijection from X into a convex subset of some linear space (and that, moreover, the affine dimension of this subset is unique), and provides examples of mixture spaces in which no, or some but not all, pairs of

distinct alternatives are separated. Let us say, more generally, that a set $Y \subseteq X$ is separated if, for all $v \in \mathbb{R}^Y$, there exists $u \in P$ such that $u|_Y = v$.⁵

Second, we introduce the following richness conditions on the domain of the social welfare function:

Definition 2. A domain $\mathcal{D} \subseteq \mathcal{P}^I$ is:

- *Indifference-rich* if, for all $x, y \in X$ and all $(U_i)_{i \in I} \in \mathcal{D}$ such that $U_i(x) = U_i(y)$ for all $i \in I$, there exist $z \in X$ and $(U'_i)_{i \in I}, (U''_i)_{i \in I} \in \mathcal{D}$ such that $U'_i|_{\{x,z\}} = U''_i|_{\{y,z\}} = \{(\gamma, \gamma) : \gamma \in U_i(x) = U_i(y)\}$ for all $i \in I$.
- *Polygon-rich* if, for all non-empty and finite $(V_i)_{i \in I} \subset (\mathbb{R}^2)^I$, there exist $x, y \in X$, $x \neq y$, and $(U_i)_{i \in I} \in \mathcal{D}$ such that $U_i|_{\{x,y\}} = \text{conv}(V_i)$ for all $i \in I$.
- *Calibration-rich* if, for all $x, y \in X$, all $(U_i)_{i \in I} \in \mathcal{D}$ and all $\lambda \in (0, 1)$, there exist $z \in X$ and $(U'_i)_{i \in I} \in \mathcal{D}$ such that, for all $i \in I$, $U'_i|_{\{x,y\}} = U_i|_{\{x,y\}}$ and $u'_i(x) = u'_i(y\lambda z)$ for all $u'_i \in U'_i$.

In words, \mathcal{D} is *indifference-rich* if, starting from any profile in \mathcal{D} in which each individual has the same utility intervals for two alternatives x and y , we can always find a third alternative z as well as a second and a third profile in \mathcal{D} in which each individual has the same utility interval for z as for x or y in the first profile and, furthermore, is indifferent between x and z in the second profile as well as between y and z in the third profile. \mathcal{D} is *polygon-rich* if every profile of (convex hulls of) finite sets of pairs of utility levels (polygon) corresponds to the restriction of some profile in \mathcal{D} to some pair of distinct alternatives. Finally, \mathcal{D} is *calibration-rich* if, starting from any two alternatives x and y , any profile in \mathcal{D} , and any coefficient λ strictly between 0 and 1, we can always find a third alternative z and a second profile in \mathcal{D} having the same restriction to the pair $\{x, y\}$ as the first profile and in which each individual is indifferent between x and $y\lambda z$ (by an appropriate calibration of the utility level of z).

Note that *polygon-richness* requires X to contain a separated pair of alternatives, and *calibration-richness* requires X to contain a separated triple of alternatives. If X is a non-empty and convex subset of some linear space (i.e. if all pairs of distinct alternatives in X are separated), then the full domain \mathcal{D} is always *indifference-rich*, is *polygon-rich* whenever X contains a separated pair of alternatives (i.e. is of affine dimension at least one), and is *calibration-rich* whenever X contains a separated triple of alternatives (i.e. is of affine dimension at least two).

Technically, *indifference-regularity* is necessary for *Independence of Irrelevant Alternatives* and *Pareto Indifference* to imply *interval-neutrality* (Lemma 1). *Polygon-richness* ensures that any profile of real intervals corresponds to the utility intervals of some alternative in some profile in the domain, and also allows the construction of some particular profiles in the proof of Theorem 1. *Calibration-richness* is needed for the last step in the proof sketch of Theorem (4). Our results thus generalize as follows.

Proposition 1. *Lemma 1 holds for any non-empty mixture space and any indifference-rich domain. Lemma 2 holds for any non-empty mixture space. Theorem 1 holds for mixture space containing a separated pair of alternatives and any polygon-rich domain. Theorem 2, Corollary 1, and Corollary 2 hold for any mixture space containing a separated triple of alternatives and any indifference-rich, polygon-rich, and calibration-rich domain.*

⁵ More precisely, Mongin [18] defines a pair $\{x, y\}$ to be separated if there exists $u \in P$ such that $u(x) \neq u(y)$. Our definition is equivalent to his for pairs but is more demanding for larger sets.

6. Conclusion

This paper constitutes a first step towards extending social choice theory to situations in which individuals may have only partially determined preferences or utilities. Specifically, we adopt a standard multi-profile setting in which individuals are endowed with vNM utility functions and introduce indeterminacy by replacing vNM utility functions by sets of vNM utility functions, such a set representing the possible utility functions the individual may have, according to the social planner. Whereas it is known that for determinate utilities, basic axioms preclude all but utilitarian aggregation rules, it turns out that the class of rules satisfying natural generalizations of these axioms is much richer for indeterminate utilities. This class, and several subclasses (including the utilitarian class) can be characterized, although moving from determinate to indeterminate utilities raises several technical and conceptual issues.

One implication of our results is that in these settings, basic axioms entail some degree of social indeterminacy: as soon as one individual has indeterminate utility, so must have society. In other words, there is no possibility for the social planner to “resolve” individual indeterminacies, as could seem desirable. One possible way out of this impossibility could be to relax the vNM assumption on social preferences (allowing for a max–min criterion, for instance). More generally, it seems worthwhile investigating whether similar results obtain when introducing indeterminacy in other social choice settings.

Appendix A. Proofs

We directly state the proofs in the general setting of Section 5.

Proof of Lemma 1. Assume X is a non-empty mixture space, \mathcal{D} is an indifference-rich domain, and F satisfies Independence of Irrelevant Alternatives and Pareto Indifference. Let $(U_i)_{i \in I}, (U'_i)_{i \in I} \in \mathcal{D}$ and $x, y \in X$ such that $U_i(x) = U'_i(y)$ for all $i \in I$. Since \mathcal{D} is indifference-rich, there exist $z \in X$ and $(U''_i)_{i \in I}, (U'''_i)_{i \in I} \in \mathcal{D}$ such that $U'_i|_{\{x,z\}} = U''_i|_{\{y,z\}} = \{(\gamma, \gamma) : \gamma \in U_i(x) = U_i(y)\}$ for all $i \in I$. Hence $F((U_i)_{i \in I})(x) = F'((U_i)_{i \in I})(x) = F''((U_i)_{i \in I})(z) = F'''((U_i)_{i \in I})(z) = F'''((U_i)_{i \in I})(y)$, where the first and third inequalities follow from Independence of Irrelevant Alternatives and the second and fourth ones from Pareto Indifference. \square

Proof of Lemma 2. Assume X is a non-empty mixture space.

(a) Let $U \in \mathcal{P}, x, y \in X$, and $\lambda \in [0, 1]$. Then by definition,

$$\begin{aligned} U(x\lambda y) &= \{u(x\lambda y) : u \in U\} \\ &= \{\lambda u(x) + (1 - \lambda)u(y) : u \in U\} \\ &\subseteq \{\lambda u(x) + (1 - \lambda)v(y) : u, v \in U\} \\ &= \lambda U(x) + (1 - \lambda)U(y). \end{aligned}$$

(b) Let $U \in \mathcal{P}, x, y \in X$, and $\lambda \in [0, 1]$. Then by definition, there exist $u, u' \in U$ such that $u(x) = \max U(x)$ and $u'(y) = \min U(y)$. Suppose $\lambda \max U(x) + (1 - \lambda) \min U(y) > \max U(x\lambda y)$. Then $\lambda \max U(x) + (1 - \lambda) \min U(y) > u(x\lambda y) = \lambda u(x) + (1 - \lambda)u(y)$. Hence, since $u(x) = \max U(x)$, it must be that $u(y) < \min U(y)$, a contradiction since $u \in U$. Similarly, suppose $\lambda \max U(x) + (1 - \lambda) \min U(y) < \min U(x\lambda y)$. Then $\lambda \max U(x) + (1 - \lambda) \min U(y) < u'(x\lambda y) = \lambda u'(x) + (1 - \lambda)u'(y)$. Hence, since $u'(y) = \min U(y)$, it must be that $u'(x) > \max U(x)$, a contradiction since $u' \in U$. \square

Proof of Theorem 1. Assume X is a mixture space containing a separated pair of alternatives and \mathcal{D} is an indifference-rich and polygon-rich domain. Clearly, if there exists a non-empty, compact, and convex set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ such that (2) holds then F is interval-neutral. Conversely, assume F is interval-neutral. Note that for a given non-empty, compact, and convex set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$, (2) holds if and only if, for all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x \in X$,

$$\begin{aligned} \max F((U_i)_{i \in I})(x) &= \max_{(\alpha, \beta, \gamma) \in \Phi} \left(\sum_{i \in I} \alpha_i \max U_i(x) - \sum_{i \in I} \beta_i \min U_i(x) + \gamma \right), \\ \min F((U_i)_{i \in I})(x) &= \min_{(\alpha, \beta, \gamma) \in \Phi} \left(\sum_{i \in I} \alpha_i \min U_i(x) - \sum_{i \in I} \beta_i \max U_i(x) + \gamma \right). \end{aligned} \tag{7}$$

Let \mathcal{K} denote the set of all non-empty and compact real intervals. Since \mathcal{D} is polygon-regular, for all $(K_i)_{i \in I} \in \mathcal{K}^I$, there exist $x \in X$ and $(U_i)_{i \in I} \in \mathcal{D}$ such that $U_i(x) = K_i$ for all $i \in I$. Hence $\{(U_i(x))_{i \in I} : (U_i)_{i \in I} \in \mathcal{D}, x \in X\} = \mathcal{K}^I$ so, by interval-neutrality, there exists a unique function $G : \mathcal{K}^I \rightarrow \mathcal{K}$ such that, for all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x \in X$,

$$F((U_i)_{i \in I})(x) = G((U_i(x))_{i \in I}).$$

Let $T = \{(r, s) \in (\mathbb{R}^I)^2 : \forall i \in I, r_i + s_i \geq 0\}$, and define the functions $\overline{G}, \underline{G} : (\mathbb{R}^I)^2 \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ by, for all $(r, s) \in (\mathbb{R}^I)^2$,

$$\begin{aligned} \overline{G}(r, s) &= \begin{cases} \max G((-s_i, r_i)_{i \in I}) & \text{if } (r, s) \in T, \\ +\infty & \text{otherwise,} \end{cases} \\ \underline{G}(r, s) &= \begin{cases} -\min G([-r_i, s_i]_{i \in I}) & \text{if } (r, s) \in T, \\ +\infty & \text{otherwise.} \end{cases} \end{aligned}$$

Clearly, $\text{dom}(\overline{G}) = \text{dom}(\underline{G}) = T$.⁶ Moreover, $\overline{G}(r, s) > -\infty$ and $\underline{G}(r, s) > -\infty$ for all $(r, s) \in (\mathbb{R}^I)^2$, so \overline{G} and \underline{G} are proper. Also note that, for all $(r, s) \in T$,

$$\overline{G}(r, s) + \underline{G}(s, r) = \max G((-s_i, r_i)_{i \in I}) - \min G([-s_i, r_i]_{i \in I}) \geq 0.$$

Finally, for all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x \in X$, we have

$$\begin{aligned} \max F((U_i)_{i \in I})(x) &= \max G((U_i(x))_{i \in I}) = \overline{G}((\max U_i(x), -\min U_i(x))_{i \in I}), \\ \min F((U_i)_{i \in I})(x) &= \min G((U_i(x))_{i \in I}) = -\underline{G}((-\min U_i(x), \max U_i(x))_{i \in I}), \end{aligned}$$

so for a given non-empty, compact, and convex set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$, (7) holds if and only if, for all $(r, s) \in T$,

$$\overline{G}(r, s) = \max_{(\alpha, \beta, \gamma) \in \Phi} (\alpha r + \beta s + \gamma), \quad \underline{G}(r, s) = \max_{(\alpha, \beta, \gamma) \in \Phi} (\alpha r + \beta s - \gamma). \tag{8}$$

Lemma 3. \overline{G} and \underline{G} are convex.

Proof. We only state the proof for \overline{G} , the argument for \underline{G} is similar. Let $(r, s), (r', s') \in T$. Since \mathcal{D} is polygon-rich, there exist $x, y \in X, x \neq y$, and $(U_i)_{i \in I} \in \mathcal{D}$ such that $U_i|_{\{x, y\}} = \text{conv}(\{w_i, w'_i\})$ for all $i \in I$, where $w_i, w'_i \in \mathbb{R}^{\{x, y\}}$ are defined by

$$\begin{aligned} w_i(x) &= -s_i, & w'_i(x) &= r_i, \\ w_i(y) &= -s'_i, & w'_i(y) &= r'_i. \end{aligned}$$

⁶ Given a function f , $\text{dom}(f)$ denotes the effective domain of f .

Note that for all $i \in I$ and all $\lambda \in [0, 1]$, we have $U_i(x\lambda y) = [-\lambda s_i - (1 - \lambda)s'_i, \lambda r_i + (1 - \lambda)r'_i]$. Hence, for all $\lambda \in [0, 1]$,

$$\begin{aligned} \overline{G}(\lambda(r, s) + (1 - \lambda)(r', s')) &= \overline{G}(\lambda r + (1 - \lambda)r', \lambda s + (1 - \lambda)s') \\ &= \max G\left(\left[-\lambda s_i - (1 - \lambda)s'_i, \lambda r_i + (1 - \lambda)r'_i\right]_{i \in I}\right) \\ &= \max G\left(\left(U_i(x\lambda y)\right)_{i \in I}\right) \\ &= \max F\left(\left(U_i\right)_{i \in I}\right)(x\lambda y) \\ &\leq \lambda \max F\left(\left(U_i\right)_{i \in I}\right)(x) + (1 - \lambda) \max F\left(\left(U_i\right)_{i \in I}\right)(y) \\ &= \lambda \max G\left(\left(U_i(x)\right)_{i \in I}\right) + (1 - \lambda) \max G\left(\left(U_i(y)\right)_{i \in I}\right) \\ &= \lambda \max G\left(\left[-s_i, r_i\right]_{i \in I}\right) + (1 - \lambda) \max G\left(\left[-s'_i, r'_i\right]_{i \in I}\right) \\ &= \lambda \overline{G}(r, s) + (1 - \lambda) \overline{G}(r', s'), \end{aligned}$$

where the inequality follows from Lemma 2(a). □

Lemma 4. \overline{G} and \underline{G} are non-decreasing.

Proof. We only state the proof for \overline{G} , the argument for \underline{G} is similar. It is sufficient to prove that for all $i \in I$, \overline{G} is non-decreasing in (r_i, s_i) . So fix some $i \in I$ and let $(r, s), (r', s') \in T$ such that $(r'_i, s'_i) \geq (r_i, s_i)$ and $(r'_j, s'_j) = (r_j, s_j)$ for all $j \in I \setminus \{i\}$. We proceed in two steps. First, we prove that $\overline{G}(r', s') \geq \overline{G}(r, s)$ whenever $r_i + s_i > 0$. To this end, we assume without loss of generality that $r'_i + s'_i \leq 2(r_i + s_i)$. Since \mathcal{D} is polygon-rich, there exist $x, y \in X, x \neq y$, and $(U_j)_{j \in I} \in \mathcal{D}$ such that $U_j|_{\{x,y\}} = \text{conv}(\{w_j, w'_j, w''_j, w'''_j\})$ for all $j \in I$, where $w_j, w'_j, w''_j, w'''_j \in \mathbb{R}^{\{x,y\}}$ are defined by

$$\begin{aligned} w_j(x) &= -s'_j, & w'_j(x) &= s'_j - 2s_j, & w''_j(x) &= r'_j, & w'''_j(x) &= 2r_j - r'_j, \\ w_j(y) &= s'_j - 2s_j, & w'_j(y) &= -s'_j, & w''_j(y) &= 2r_j - r'_j, & w'''_j(y) &= r'_j. \end{aligned}$$

Note that for all $j \in I$, we have $U_j(x) = U_j(y) = [-s'_j, r'_j]$ and $U_j(x\frac{1}{2}y) = [-s_j, r_j]$. Hence,

$$\begin{aligned} \overline{G}(r, s) &= \max G\left(\left[-s_j, r_j\right]_{j \in I}\right) \\ &= \max G\left(\left(U_j\left(x\frac{1}{2}y\right)\right)_{j \in I}\right) \\ &= \max F\left(\left(U_j\right)_{j \in I}\right)\left(x\frac{1}{2}y\right) \\ &\leq \frac{1}{2} \max F\left(\left(U_j\right)_{j \in I}\right)(x) + \frac{1}{2} \max F\left(\left(U_j\right)_{j \in I}\right)(y) \\ &= \frac{1}{2} \max G\left(\left(U_j(x)\right)_{j \in I}\right) + \frac{1}{2} \max G\left(\left(U_j(y)\right)_{j \in I}\right) \\ &= \frac{1}{2} \max G\left(\left[-s'_j, r'_j\right]_{j \in I}\right) + \frac{1}{2} \max G\left(\left[-s'_j, r'_j\right]_{j \in I}\right) \\ &= \overline{G}(r', s'), \end{aligned}$$

where the inequality follows from Lemma 2(a).

Second, we prove that $\overline{G}(r', s') \geq \overline{G}(r, s)$ whenever $r_i + s_i = 0$. To this end, suppose $\overline{G}(r', s') < \overline{G}(r, s)$. Clearly, it must then be that $r'_i + s'_i > 0$. Since \mathcal{D} is polygon-rich, there exist $x, y \in X$, $x \neq y$, and $(U_j)_{j \in I} \in \mathcal{D}$ such that $U_j|_{\{x,y\}} = \text{conv}(\{w_j, w'_j\})$ for all $j \in I$, where $w_j, w'_j \in \mathbb{R}^{\{x,y\}}$ are defined by

$$\begin{aligned} w_j(x) &= -s_j, & w'_j(x) &= r_j, \\ w_j(y) &= -s'_j, & w'_j(y) &= r'_j. \end{aligned}$$

Note that for all $j \in I$ and all $\lambda \in [0, 1]$, we have $U_j(x\lambda y) = [-\lambda s_j - (1-\lambda)s'_j, \lambda r_j + (1-\lambda)r'_j]$. Hence,

$$\begin{aligned} \max F((U_j)_{j \in I})(x) &= \max G((U_j(x))_{j \in I}) \\ &= \max G((-s_j, r_j)_{j \in I}) \\ &= \overline{G}(r, s) \\ &> \overline{G}(r', s') \\ &= \max G((-s'_j, r'_j)_{j \in I}) \\ &= \max G((U_j(y))_{j \in I}) \\ &= \max F((U_j)_{j \in I})(y), \end{aligned}$$

so there exists $\lambda \in (0, 1)$ such that $\lambda \max F((U_j)_{j \in I})(x) + (1 - \lambda) \min F((U_i)_{i \in I})(y) > \max F((U_j)_{j \in I})(y)$. Moreover,

$$\begin{aligned} \max F((U_j)_{j \in I})(x\lambda y) &= \max G((U_j(x\lambda y))_{j \in I}) \\ &= \max G([- \lambda s_j - (1-\lambda)s'_j, \lambda r_j + (1-\lambda)r'_j]_{j \in I}) \\ &= \overline{G}(\lambda(r, s) + (1-\lambda)(r', s')) \\ &\leq \overline{G}(r', s') \\ &= \max F((U_j)_{j \in I})(y), \end{aligned}$$

where the inequality follows from the first step. It follows that $\lambda \max F((U_j)_{j \in I})(x) + (1 - \lambda) \min F((U_j)_{j \in I})(y) > \max F((U_j)_{j \in I})(x\lambda y)$, a contradiction by Lemma 2(b). \square

Lemma 5. \overline{G} and \underline{G} are continuous.

Proof. We only state the proof for \overline{G} , the argument for \underline{G} is similar. By Lemma 3, \overline{G} is upper semi-continuous since T is a polyhedral cone (Rockafellar [20, Theorem 10.2, Theorem 20.5]), so it is sufficient to prove that \overline{G} is lower semi-continuous, i.e. that $\text{cl } \overline{G} = \overline{G}$.⁷ By definition, $\text{cl } \overline{G} \leq \overline{G}$. Conversely, let $(r, s) \in (\mathbb{R}^I)^2$. If $(r, s) \notin T$ then $\text{cl } \overline{G}(r, s) = \overline{G}(r, s) = +\infty$ since T is closed. If $(r, s) \in T$ then let $(r', s') \in (\mathbb{R}^I)^2$ such that $r'_i > r_i$ and $s'_i > s_i$ for all $i \in I$. Then (r', s') belongs to the relative interior of T and, hence, $\text{cl } \overline{G}(r, s) = \lim_{\lambda \rightarrow 0^+} \overline{G}((1-\lambda)(r, s) + \lambda(r', s'))$ (Rockafellar [20, Theorem 7.5]). By Lemma 4, we have $\overline{G}(r, s) \leq \overline{G}((1-\lambda)(r, s) + \lambda(r', s'))$ for all $\lambda \in [0, 1]$ and, hence, $\overline{G}(r, s) \leq \text{cl } \overline{G}(r, s)$. \square

Lemma 6. For all $(r, s) \in T$ and all $\mu > 1$, $\overline{G}(\mu(r, s)) + \underline{G}(\mu(r, s)) \leq \mu(\overline{G}(r, s) + \underline{G}(r, s))$.

⁷ Given a function f , $\text{cl } f$ denotes the closure of f .

Proof. Let $(r, s) \in T$ and $\mu > 1$. Since \mathcal{D} is polygon-rich, there exist $x, y \in X$, $x \neq y$, and $(U_i)_{i \in I} \in \mathcal{D}$ such that $U_i|_{\{x,y\}} = \text{conv}(\{w_i, w'_i\})$ for all $i \in I$, where $w_i, w'_i \in \mathbb{R}^{(x,y)}$ are defined by

$$\begin{aligned} w_i(x) &= -\mu s_i, & w'_i(x) &= \mu r_i, \\ w_i(y) &= \mu s_i, & w'_i(y) &= -\mu r_i. \end{aligned}$$

Note that for all $i \in I$, we have $U_i(x) = [-\mu s_i, \mu r_i]$, $U_i(y) = [-\mu r_i, \mu s_i]$, $U_i(x \frac{1}{2} y) = \{0\}$, $U_i(x \frac{1}{\mu} (x \frac{1}{2} y)) = [-s_i, r_i]$, and $U_i(y \frac{1}{\mu} (x \frac{1}{2} y)) = [-r_i, s_i]$. Hence,

$$\begin{aligned} \frac{\mu + 1}{2\mu} \overline{G}(\mu(r, s)) - \frac{\mu - 1}{2\mu} \underline{G}(\mu(r, s)) &= \frac{\mu + 1}{2\mu} \max F((U_i)_{i \in I})(x) \\ &\quad + \frac{\mu - 1}{2\mu} \min F((U_i)_{i \in I})(y) \\ &\leq \max F((U_i)_{i \in I})\left(x \frac{\mu + 1}{2\mu} y\right) \\ &= \max F((U_i)_{i \in I})\left(x \frac{1}{\mu} \left(x \frac{1}{2} y\right)\right) \\ &= \overline{G}(r, s), \end{aligned}$$

where the inequality follows from Lemma 2(b). Similarly,

$$\begin{aligned} \frac{\mu - 1}{2\mu} \overline{G}(\mu(r, s)) - \frac{\mu + 1}{2\mu} \underline{G}(\mu(r, s)) &= \frac{\mu - 1}{2\mu} \max F((U_i)_{i \in I})(x) \\ &\quad + \frac{\mu + 1}{2\mu} \min F((U_i)_{i \in I})(y) \\ &\geq \min F((U_i)_{i \in I})\left(x \frac{\mu - 1}{2\mu} y\right) \\ &= \min F((U_i)_{i \in I})\left(y \frac{1}{\mu} \left(x \frac{1}{2} y\right)\right) \\ &= -\underline{G}(r, s), \end{aligned}$$

where the inequality follows again from Lemma 2(b). Hence,

$$\begin{aligned} \overline{G}(r, s) + \underline{G}(r, s) &\geq \frac{\mu + 1}{2\mu} \overline{G}(\mu(r, s)) - \frac{\mu - 1}{2\mu} \underline{G}(\mu(r, s)) - \frac{\mu - 1}{2\mu} \overline{G}(\mu(r, s)) \\ &\quad + \frac{\mu + 1}{2\mu} \underline{G}(\mu(r, s)) \\ &= \frac{1}{\mu} (\overline{G}(\mu(r, s)) + \underline{G}(\mu(r, s))), \end{aligned}$$

so $\overline{G}(\mu(r, s)) + \underline{G}(\mu(r, s)) \leq \mu(\overline{G}(r, s) + \underline{G}(r, s))$. \square

Let $\overline{G}0^+, \underline{G}0^+ : (\mathbb{R}^J)^2 \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ denote the recession functions of \overline{G} and \underline{G} , respectively, i.e. (Rockafellar [20, Theorem 8.5]) for all $(r, s) \in (\mathbb{R}^J)^2$,

$$\overline{G}0^+(r, s) = \lim_{\mu \rightarrow +\infty} \frac{\overline{G}(\mu(r, s))}{\mu}, \quad \underline{G}0^+(r, s) = \lim_{\mu \rightarrow +\infty} \frac{\underline{G}(\mu(r, s))}{\mu}.$$

$\overline{G}0^+$ and $\underline{G}0^+$ are positively homogeneous, proper convex functions by definition, and are closed since \overline{G} and \underline{G} are closed. Also note that $\overline{G}0^+$ and $\underline{G}0^+$ are non-decreasing by Lemma 4.

Lemma 7. $\text{dom}(\overline{G}0^+) = T$ and $\underline{G}0^+ = \overline{G}0^+$.

Proof. Let $(r, s) \in (\mathbb{R}^I)^2$. If $(r, s) \notin T$ then, clearly, $\overline{G}0^+(r, s) = \underline{G}0^+(r, s) = +\infty$. Hence it is sufficient to show that if $(r, s) \in T$ then $\lim_{\mu \rightarrow +\infty} \frac{\overline{G}(\mu(r,s))}{\mu} = \lim_{\mu \rightarrow +\infty} \frac{\underline{G}(\mu(r,s))}{\mu} < +\infty$. So let $(r, s) \in T$. Since $\frac{\overline{G}(\mu(r,s))}{\mu}$ and $\frac{\underline{G}(\mu(r,s))}{\mu}$ are non-decreasing functions of μ (Rockafellar [20, Theorem 23.1]), and since the sum of these two functions is bounded above by Lemma 6, we have $\lim_{\mu \rightarrow +\infty} \frac{\overline{G}(\mu(r,s))}{\mu} < +\infty$ and $\lim_{\mu \rightarrow +\infty} \frac{\underline{G}(\mu(r,s))}{\mu} < +\infty$. Moreover, for all $\mu > 1$, defining x, y, U_i, w_i , and w'_i as in the proof of Lemma 6 yields

$$\begin{aligned} \frac{1}{2}\overline{G}(\mu(r, s)) - \frac{1}{2}\underline{G}(\mu(r, s)) &= \frac{1}{2} \max F((U_i)_{i \in I})(x) + \frac{1}{2} \min F((U_i)_{i \in I})(y) \\ &\in \left[\min F((U_i)_{i \in I})\left(x \frac{1}{2}y\right), \max F((U_i)_{i \in I})\left(x \frac{1}{2}y\right) \right] \\ &= [-\underline{G}(0, 0), \overline{G}(0, 0)], \end{aligned}$$

by Lemma 2(b), so $-\frac{2}{\mu}\underline{G}(0, 0) \leq \frac{1}{\mu}\overline{G}(\mu(r, s)) - \frac{1}{\mu}\underline{G}(\mu(r, s)) \leq \frac{2}{\mu}\overline{G}(0, 0)$ and, hence, $\lim_{\mu \rightarrow +\infty} \frac{\overline{G}(\mu(r,s))}{\mu} = \lim_{\mu \rightarrow +\infty} \frac{\underline{G}(\mu(r,s))}{\mu}$. \square

Lemma 8. $\overline{G}, \underline{G}, \overline{G}0^+$, and $\underline{G}0^+$ are Lipschitzian.

Proof. We only state the proof for \overline{G} and $\overline{G}0^+$, the argument for \underline{G} and $\underline{G}0^+$ is similar. First, for all $(r, s) \in (\mathbb{R}^I)^2$, let $T(r, s) = ((-\min\{-r_i, s_i\}, \max\{-r_i, s_i\})_{i \in I})$. Note that $T(r, s) \in T$ for all $(r, s) \in (\mathbb{R}^I)^2$ and $T(r, s) = (r, s)$ for all $(r, s) \in T$. Define the function $\overline{g} : (\mathbb{R}^I)^2 \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ by, for all $(r, s) \in (\mathbb{R}^I)^2$, $\overline{g}(r, s) = \overline{G}(T(r, s))$. Clearly, $\text{dom}(\overline{g}) = (\mathbb{R}^I)^2$ and, for all $(r, s) \in T$, $\overline{g}(r, s) = \overline{G}(r, s)$. Moreover, \overline{g} is convex since, for all $(r, s), (r', s') \in (\mathbb{R}^I)^2$ and all $\lambda \in [0, 1]$,

$$\begin{aligned} &\overline{g}(\lambda(r, s) + (1 - \lambda)(r', s')) \\ &= \overline{G} \left(\left(\begin{array}{c} -\min\{\lambda(-r_i) + (1 - \lambda)(-r'_i), \lambda s_i + (1 - \lambda)s'_i\}, \\ \max\{\lambda(-r_i) + (1 - \lambda)(-r'_i), \lambda s_i + (1 - \lambda)s'_i\} \end{array} \right)_{i \in I} \right) \\ &\leq \overline{G} \left(\left(\begin{array}{c} -(\lambda \min\{-r_i, s_i\} + (1 - \lambda) \min\{-r'_i, s'_i\}), \\ \lambda \max\{-r_i, s_i\} + (1 - \lambda) \max\{-r'_i, s'_i\} \end{array} \right)_{i \in I} \right) \\ &= \overline{G} \left(\begin{array}{c} \lambda(-\min\{-r_i, s_i\}, \max\{-r_i, s_i\})_{i \in I} \\ + (1 - \lambda)(-\min\{-r'_i, s'_i\}, \max\{-r'_i, s'_i\})_{i \in I} \end{array} \right) \\ &\leq \lambda \overline{G}((-\min\{-r_i, s_i\}, \max\{-r_i, s_i\})_{i \in I}) \\ &\quad + (1 - \lambda) \overline{G}((-\min\{-r'_i, s'_i\}, \max\{-r'_i, s'_i\})_{i \in I}) \\ &= \lambda \overline{g}(r, s) + (1 - \lambda) \overline{g}(r', s'), \end{aligned}$$

where the first inequality follows from Lemma 4 and the second one from Lemma 3. Now, suppose \bar{G} is not Lipschitzian. Then \bar{g} is not Lipschitzian either. Hence, since \bar{g} is finite and convex, there must exist $(r, s) \in (\mathbb{R}^I)^2$ such that $\bar{g}0^+(r, s) = +\infty$ (Rockafellar [20, Theorem 10.5]), i.e. $\bar{G}0^+(T(r, s)) = +\infty$, a contradiction by Lemma 7. Finally, note that for all $(r, s) \in (\mathbb{R}^I)^2$, $\bar{g}0^+(r, s) = \bar{G}0^+(T(r, s)) < +\infty$ by Lemma 7. Hence $\bar{g}0^+$ is Lipschitzian since it is its own recession function (Rockafellar [20, Theorem 10.5]), so $\bar{G}0^+$ is Lipschitzian. \square

Lemma 9. For all $(r, s), (r', s') \in (\mathbb{R}^I)^2$, if $\bar{G}0^{+'}((r, s), (r', s')) = -\bar{G}0^{+'}((r, s), -(r', s'))$ then⁸

$$\begin{aligned} \bar{G}0^{+'}((r, s), (r', s')) &= \lim_{\mu \rightarrow +\infty} \bar{G}'(\mu(r, s), (r', s')) \\ &= \lim_{\mu \rightarrow +\infty} -\bar{G}'(\mu(r, s), -(r', s')) \\ &= \lim_{\mu \rightarrow +\infty} \underline{G}'(\mu(r, s), (r', s')) \\ &= \lim_{\mu \rightarrow +\infty} -\underline{G}'(\mu(r, s), -(r', s')). \end{aligned}$$

Proof. We only state the proof for \bar{G} , the argument for \underline{G} is similar, given Lemma 7. Let $(r, s), (r', s') \in (\mathbb{R}^I)^2$. If $(r, s) \notin T$ then the lemma is trivially true (all directional derivatives are equal to $+\infty$), so assume $(r, s) \in T$. Then, by definition of $\bar{G}0^{+'}$, for all $\varepsilon > 0$, there exists $\delta_0 > 0$ such that

$$\frac{\bar{G}0^+((r, s) + \delta_0(r', s')) - \bar{G}0^+(r, s)}{\delta_0} \leq \bar{G}0^{+'}((r, s), (r', s')) + \varepsilon$$

and, hence,

$$\lim_{\mu \rightarrow +\infty} \frac{\bar{G}(\mu(r, s) + \mu\delta_0(r', s')) - \bar{G}(\mu(r, s))}{\mu\delta_0} \leq \bar{G}0^{+'}((r, s), (r', s')) + \varepsilon.$$

Hence, for all $\varepsilon > 0$, there exist $\delta_0 > 0$ and $\mu_0 > 1$ such that, for all $\mu \geq \mu_0$,

$$\frac{\bar{G}(\mu(r, s) + \mu\delta_0(r', s')) - \bar{G}(\mu(r, s))}{\mu\delta_0} \leq \bar{G}0^{+'}((r, s), (r', s')) + \varepsilon.$$

Moreover, since $\mu(r, s) + \delta_0(r', s') = (1 - \frac{1}{\mu})(\mu(r, s)) + \frac{1}{\mu}(\mu(rs) + \mu\delta_0(r', s'))$, we have

$$\bar{G}(\mu(r, s) + \delta_0(r', s')) \leq \left(1 - \frac{1}{\mu}\right)\bar{G}(\mu(r, s)) + \frac{1}{\mu}\bar{G}(\mu(rs) + \mu\delta_0(r', s'))$$

by Lemma 3 and, hence,

$$\frac{\bar{G}(\mu(r, s) + \delta_0(r', s')) - \bar{G}(\mu(r, s))}{\delta_0} \leq \frac{\bar{G}(\mu(r, s) + \mu\delta_0(r', s')) - \bar{G}(\mu(r, s))}{\mu\delta_0}.$$

Hence, for all $\varepsilon > 0$, there exist $\delta_0 > 0$ and $\mu_0 > 1$ such that, for all $\mu \geq \mu_0$,

$$\frac{\bar{G}(\mu(r, s) + \delta_0(r', s')) - \bar{G}(\mu(r, s))}{\delta_0} \leq \bar{G}0^{+'}((r, s), (r', s')) + \varepsilon$$

⁸ Given a function f and a point $x \in \text{dom}(f)$, $f'(x, y)$ denotes the (one-sided) directional derivative of f at x in direction y , i.e. $f'(x, y) = \lim_{\delta \rightarrow 0^+} \frac{f(x+\delta y) - f(x)}{\delta}$ if $x \in \text{dom}(f)$ and $f'(x, y) = +\infty$ otherwise.

and, hence, for all $\delta \in (0, \delta_0)$,

$$\frac{\overline{G}(\mu(r, s) + \delta(r', s')) - \overline{G}(\mu(r, s))}{\delta} \leq \overline{G}0^{+'}((r, s), (r', s')) + \varepsilon$$

by Lemma 3 (Rockafellar [20, Theorem 23.1]). Hence, by definition of \overline{G}' , for all $\varepsilon > 0$, there exists $\mu_0 > 1$ such that $\overline{G}'(\mu(r, s), (r', s')) \leq \overline{G}0^{+'}((r, s), (r', s')) + \varepsilon$ for all $\mu \geq \mu_0$.

Now, assume $\overline{G}0^{+'}((r, s), (r', s')) = -\overline{G}0^{+'}((r, s), -(r', s'))$. Then, by the preceding paragraph, for all $\varepsilon > 0$, there exists $\mu_0 > 1$ such that, for all $\mu \geq \mu_0$,

$$\begin{aligned} \overline{G}'(\mu(r, s), (r', s')) - \varepsilon &\leq \overline{G}0^{+'}((r, s), (r', s')) \\ &= -\overline{G}0^{+'}((r, s), -(r', s')) \\ &\leq -\overline{G}'(\mu(r, s), -(r', s')) + \varepsilon \\ &\leq \overline{G}(\mu(r, s), (r', s')) + \varepsilon \end{aligned}$$

(where the last inequality follows from Rockafellar [20, Theorem 23.1]), so we obtain $\lim_{\mu \rightarrow +\infty} \overline{G}'(\mu(r, s), (r', s')) = \lim_{\mu \rightarrow +\infty} -\overline{G}'(\mu(r, s), -(r', s')) = \overline{G}0^{+'}((r, s), (r', s'))$ by passing to the limit as $\varepsilon \rightarrow 0_+$. \square

Let $\overline{G}^*, \underline{G}^* : (\mathbb{R}^I)^2 \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ denote the conjugate functions of \overline{G} and \underline{G} , respectively, i.e. for all $(\alpha, \beta) \in (\mathbb{R}^I)^2$,

$$\overline{G}^*(\alpha, \beta) = \sup_{(r,s) \in T} (\alpha r + \beta s - \overline{G}(r, s)), \quad \underline{G}^*(\alpha, \beta) = \sup_{(r,s) \in T} (\alpha r + \beta s - \underline{G}(r, s)).$$

Since \overline{G} and \underline{G} are closed proper convex functions, so are \overline{G}^* and \underline{G}^* (Rockafellar [20, Theorem 12.2]). Moreover, \overline{G}^* and \underline{G}^* are clearly bounded below since, for all $(\alpha, \beta) \in (\mathbb{R}^I)^2$, $\overline{G}^*(\alpha, \beta) \geq -\overline{G}(0, 0)$ and $\underline{G}^*(\alpha, \beta) \geq -\underline{G}(0, 0)$.

Let $C = \{(-\eta, -\eta) : \eta \in \mathbb{R}_+^I\} \subset (\mathbb{R}_+^I)^2$. Clearly, C is a non-empty, closed, and convex cone containing no line and, moreover, we have $C = T^\circ$.⁹ Let $L \subset (\mathbb{R}^I)^2$ be the set of points where $\overline{G}0^+$ is differentiable. Clearly, $\text{cl}(L) = T$ (Rockafellar [20, Theorem 25.5]), so L is non-empty.¹⁰ Let $E = \{\nabla \overline{G}0^+(r, s) : (r, s) \in L\}$ and $M = \text{cl}(\text{conv}(E))$. By Lemmas 4 and 8, E is a non-empty and bounded subset of $(\mathbb{R}_+^I)^2$ and, hence, M is a non-empty, compact, and convex subset of $(\mathbb{R}_+^I)^2$.

Lemma 10. For all $(\alpha, \beta) \in M + C$, $\overline{G}^*(\alpha, \beta) + \underline{G}^*(\alpha, \beta) \leq 0$.

Proof. We claim that $\overline{G}^*(\alpha, \beta) + \underline{G}^*(\alpha, \beta) \leq 0$ for all $(\alpha, \beta) \in E$. If this is true then we have $\overline{G}^*(\alpha, \beta) + \underline{G}^*(\alpha, \beta) \leq 0$ for all $(\alpha, \beta) \in M$ since $\overline{G}^* + \underline{G}^*$ is closed (Rockafellar [20, Theorem 9.3]). Moreover, for all $\eta \in \mathbb{R}_+^I$, we have $\overline{G}^*(\alpha - \eta, \beta - \eta) = \sup_{(r,s) \in T} (\alpha r + \beta s - \eta(r + s) - \overline{G}(r, s)) \leq \overline{G}^*(\alpha, \beta)$ and $\underline{G}^*(\alpha - \eta, \beta - \eta) = \sup_{(r,s) \in T} (\alpha r + \beta s - \eta(r + s) - \underline{G}(r, s)) \leq \underline{G}^*(\alpha, \beta)$ since $r + s \geq 0$ for all $(r, s) \in T$. Hence $\overline{G}^*(\alpha, \beta) + \underline{G}^*(\alpha, \beta) \leq 0$ for all $(\alpha, \beta) \in M + C$.

⁹ Given a cone S , S° denotes the polar cone of S , i.e. $S^\circ = \{y : \forall s \in S, \langle y, s \rangle \leq 0\}$.

¹⁰ Given a set S , $\text{cl}(S)$ denotes the closure of S .

To prove the claim, let $(\alpha, \beta) \in E$. Since \bar{G}^* and \underline{G}^* are closed, it is sufficient to find two sequences $(\bar{\alpha}_\mu, \bar{\beta}_\mu)_{\mu \geq 1}$ and $(\underline{\alpha}_\mu, \underline{\beta}_\mu)_{\mu \geq 1}$ in $(\mathbb{R}^I)^2$ such that $\lim_{\mu \rightarrow +\infty} (\bar{\alpha}_\mu, \bar{\beta}_\mu) = \lim_{\mu \rightarrow +\infty} (\underline{\alpha}_\mu, \underline{\beta}_\mu) = (\alpha, \beta)$ and $\lim_{\mu \rightarrow +\infty} \bar{G}^*(\bar{\alpha}_\mu, \bar{\beta}_\mu) + \lim_{\mu \rightarrow +\infty} \underline{G}^*(\underline{\alpha}_\mu, \underline{\beta}_\mu) \leq 0$. Moreover, since \bar{G}^* and \underline{G}^* are bounded below, a sufficient condition for $\lim_{\mu \rightarrow +\infty} \bar{G}^*(\bar{\alpha}_\mu, \bar{\beta}_\mu) + \lim_{\mu \rightarrow +\infty} \underline{G}^*(\underline{\alpha}_\mu, \underline{\beta}_\mu) \leq 0$ is that $\bar{G}^*(\bar{\alpha}_\mu, \bar{\beta}_\mu) + \underline{G}^*(\underline{\alpha}_\mu, \underline{\beta}_\mu) \leq 0$ for all $\mu \geq 1$.

In order to construct these sequences, note that since $(\alpha, \beta) \in E$, we have $(\alpha, \beta) = \nabla \bar{G}0^+(r, s)$ for some $(r, s) \in L$ by definition. Clearly, (r, s) must then belong to the interior of T (Rockafellar [20, Corollary 25.1.1]). Hence, for all $\mu \geq 1$, $\mu(r, s)$ also belongs to the interior of T , so $\partial \bar{G}(\mu(r, s))$ is non-empty and compact (Rockafellar [20, Theorem 23.4]).¹¹ It follows that there exists $(\bar{\alpha}_\mu, \bar{\beta}_\mu) \in \partial \bar{G}(\mu(r, s))$ such that $\bar{G}'(\mu(r, s), -(r, s)) = -\bar{\alpha}_\mu r - \bar{\beta}_\mu s$ since $\bar{G}'(\mu(r, s), \cdot)$ is the support function of $\partial \bar{G}(\mu(r, s))$ (Rockafellar [20, Theorem 23.2, Theorem 23.4]). Hence we have $\bar{G}(\mu(r, s)) + \bar{G}^*(\bar{\alpha}_\mu, \bar{\beta}_\mu) = \mu(\bar{\alpha}_\mu r + \bar{\beta}_\mu s)$ (Rockafellar [20, Theorem 23.5]) and, hence,

$$\begin{aligned} \bar{G}^*(\bar{\alpha}_\mu, \bar{\beta}_\mu) &= -\bar{G}(\mu(r, s)) - \mu \bar{G}'(\mu(r, s), -(r, s)) \\ &= -\bar{G}(\mu(r, s)) - \mu \lim_{\varepsilon \downarrow 0} \frac{\bar{G}((\mu - \varepsilon)(r, s)) - \bar{G}(\mu(r, s))}{\varepsilon} \\ &= \lim_{\varepsilon \downarrow 0} \frac{(\mu - \varepsilon)\bar{G}(\mu(r, s)) - \mu \bar{G}((\mu - \varepsilon)(r, s))}{\varepsilon}. \end{aligned}$$

Similarly, there exists $(\underline{\alpha}_\mu, \underline{\beta}_\mu) \in \partial \underline{G}(\mu(r, s))$ such that

$$\underline{G}^*(\underline{\alpha}_\mu, \underline{\beta}_\mu) = \lim_{\varepsilon \downarrow 0} \frac{(\mu - \varepsilon)\underline{G}(\mu(r, s)) - \mu \underline{G}((\mu - \varepsilon)(r, s))}{\varepsilon}.$$

Hence,

$$\begin{aligned} \bar{G}^*(\bar{\alpha}_\mu, \bar{\beta}_\mu) + \underline{G}^*(\underline{\alpha}_\mu, \underline{\beta}_\mu) &= \lim_{\varepsilon \downarrow 0} \frac{(\mu - \varepsilon)(\bar{G}(\mu(r, s)) + \underline{G}(\mu(r, s))) - \mu(\bar{G}((\mu - \varepsilon)(r, s)) + \underline{G}((\mu - \varepsilon)(r, s)))}{\varepsilon} \\ &\leq 0 \end{aligned}$$

by Lemma 6. Moreover, $\bar{G}0^+((r, s), \cdot)$ is linear since $(r, s) \in L$ (Rockafellar [20, Theorem 25.2]) and, hence, $(\bar{G}'(\mu(r, s), \cdot))_{\mu \geq 1}$ and $(\underline{G}'(\mu(r, s), \cdot))_{\mu \geq 1}$ converge pointwise to $\bar{G}0^+((r, s), \cdot)$ as $\mu \rightarrow +\infty$ by Lemma 9. Since $\bar{G}0^+((r, s), \cdot)$ is the support function of $\partial \bar{G}0^+(r, s) = \{(\alpha, \beta)\}$, it follows that $\lim_{\mu \rightarrow +\infty} (\bar{\alpha}_\mu, \bar{\beta}_\mu) = \lim_{\mu \rightarrow +\infty} (\underline{\alpha}_\mu, \underline{\beta}_\mu) = (\alpha, \beta)$ (Schneider [21, Theorem 1.8.11, Theorem 1.8.12]). \square

Lemma 11. $\text{dom}(\bar{G}^*) = \text{dom}(\underline{G}^*) = M + C$.

Proof. Since \bar{G}^* and \underline{G}^* are proper, we have $M + C \subseteq \text{dom}(\bar{G}^*) \cap \text{dom}(\underline{G}^*)$ by Lemma 10. Hence it is sufficient to prove that $\text{cl}(\text{dom}(\bar{G}^*)) = \text{cl}(\text{dom}(\underline{G}^*)) = M + C$. To this end, note that by definition of \bar{G}^* , $\bar{G}0^+$, \underline{G}^* , and $\underline{G}0^+$, we have

¹¹ Given a function f and a point x , $\partial f(x)$ denotes the subdifferential of f at x , i.e. $\partial f(x) = \{x^*: \forall y, f(y) \geq f(x) + (y - x)x^*\}$.

$$\begin{aligned} \text{cl}(\text{dom}(\overline{G}^*)) &= \{(\alpha, \beta) \in (\mathbb{R}^I)^2: \forall (r, s) \in (\mathbb{R}^I)^2, \alpha r + \beta s \leq \overline{G}0^+(r, s)\}, \\ \text{cl}(\text{dom}(\underline{G}^*)) &= \{(\alpha, \beta) \in (\mathbb{R}^I)^2: \forall (r, s) \in (\mathbb{R}^I)^2, \alpha r + \beta s \leq \underline{G}0^+(r, s)\} \end{aligned}$$

(Rockafellar [20, Corollary 13.2.1, Theorem 13.3]), so $\text{cl}(\text{dom}(\overline{G}^*)) = \text{cl}(\text{dom}(\underline{G}^*))$ by Lemma 7. Moreover, since $\text{dom}(\overline{G}0^+) = T$, we have $0^+ \text{cl}(\text{dom}(\overline{G}^*)) = \{(\alpha, \beta) \in (\mathbb{R}^I)^2: \forall (r, s) \in T, \alpha r + \beta s \leq 0\} = T^\circ = C$.¹² Hence $\text{cl}(\text{dom}(\overline{G}^*))$ contains no line, so

$$\text{cl}(\text{dom}(\overline{G}^*)) = \text{cl}(\text{conv}(\text{exp}(\text{cl}(\text{dom}(\overline{G}^*)))) + C$$

(Rockafellar [20, Theorem 18.7]).¹³ Moreover, $\text{exp}(\text{cl}(\text{dom}(\overline{G}^*))) = E$ (Rockafellar [20, Corollary 25.1.3]) and, hence, $\text{cl}(\text{dom}(\overline{G}^*)) = M + C$ since E is bounded (Rockafellar [20, Corollary 9.1.1]). □

Let $C' = C \times \mathbb{R}_+ \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$. Clearly, C' is a non-empty, closed, and convex cone containing no line. Let $\overline{L}, \underline{L} \subset (\mathbb{R}^I)^2$ be the sets of points where \overline{G} and \underline{G} are differentiable, respectively. Clearly, $\text{cl}(\overline{L}) = \text{cl}(\underline{L}) = T$ (Rockafellar [20, Theorem 25.5]), so \overline{L} and \underline{L} are non-empty. Let $\overline{E} = \{\nabla \overline{G}(r, s): (r, s) \in \overline{L}\}$ and $\underline{E} = \{\nabla \underline{G}(r, s): (r, s) \in \underline{L}\}$. By Lemmas 4 and 8, \overline{E} and \underline{E} are non-empty and bounded subsets of $(\mathbb{R}_+^I)^2$. Moreover, we have $\overline{E} \subseteq \text{dom}(\overline{G}^*)$ and $\underline{E} \subseteq \text{dom}(\underline{G}^*)$ (Rockafellar [20, Theorem 23.5]) and, hence, the sets $\overline{E}' = \{(\alpha, \beta, \overline{G}^*(\alpha, \beta)): (\alpha, \beta) \in \overline{E}\}$ and $\underline{E}' = \{(\alpha, \beta, \underline{G}^*(\alpha, \beta)): (\alpha, \beta) \in \underline{E}\}$ are non-empty and bounded subsets of $(\mathbb{R}_+^I)^2 \times \mathbb{R}$ since \overline{G}^* and \underline{G}^* are bounded below and above by Lemma 10. Hence the sets $\overline{M}' = \text{cl}(\text{conv}(\overline{E}'))$ and $\underline{M}' = \text{cl}(\text{conv}(\underline{E}'))$ are non-empty, compact, and convex subsets of $(\mathbb{R}_+^I)^2 \times \mathbb{R}$.

Lemma 12. For all non-empty, compact, and convex set $\overline{\Phi} \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$, $\overline{M}' \subseteq \overline{\Phi} \subseteq \overline{M}' + C'$ if and only if, for all $(r, s) \in T$, $\overline{G}(r, s) = \max_{(\alpha, \beta, \gamma) \in \overline{\Phi}} (\alpha r + \beta s - \gamma)$. Similarly, for all non-empty, compact, and convex set $\underline{\Phi} \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$, $\underline{M}' \subseteq \underline{\Phi} \subseteq \underline{M}' + C'$ if and only if, for all $(r, s) \in T$, $\underline{G}(r, s) = \max_{(\alpha, \beta, \gamma) \in \underline{\Phi}} (\alpha r + \beta s - \gamma)$.

Proof. We only state the proof for \overline{G} , the argument for \underline{G} is similar. Since \overline{G} is closed, it is the conjugate function of \overline{G}^* (Rockafellar [20, Theorem 12.2]), i.e. for all $(r, s) \in T$,¹⁴

$$\overline{G}(r, s) = \sup_{(\alpha, \beta) \in \text{dom}(\overline{G}^*)} (\alpha r + \beta s - \overline{G}^*(\alpha, \beta)) = \sup_{(\alpha, \beta, \gamma) \in \text{epi}(\overline{G}^*)} (\alpha r + \beta s - \gamma).$$

We now prove that $\text{epi}(\overline{G}^*) = \overline{M}' + C'$. First, we clearly have $0^+ \text{epi}(\overline{G}^*) \subseteq 0^+ \text{dom}(\overline{G}^*) \times \mathbb{R} = C \times \mathbb{R}$. Moreover, since \overline{G}^* is bounded below, we have in fact $0^+ \text{epi}(\overline{G}^*) \subseteq C \times \mathbb{R}_+ = C'$. Conversely, since $\overline{G}^*(\alpha - \eta, \beta - \eta) \leq \overline{G}^*(\alpha, \beta)$ for all $(\alpha, \beta) \in \text{dom}(\overline{G}^*)$ and all $\eta \in \mathbb{R}_+^I$ (see the proof of Lemma 10), we have $C' \subseteq 0^+ \text{epi}(\overline{G}^*)$. Hence $0^+ \text{epi}(\overline{G}^*) = C'$ and, hence, $\text{epi}(\overline{G}^*)$ contains no line, so we have $\text{epi}(\overline{G}^*) = \text{cl}(\text{conv}(\text{exp}(\text{epi}(\overline{G}^*)))) + C'$ since \overline{G}^* is closed (Rockafellar [20, Theorem 18.7]). Moreover, $\text{exp}(\text{epi}(\overline{G}^*)) = \overline{E}'$ (Rockafellar [20, Corollary 25.1.2]) and, hence, $\text{epi}(\overline{G}^*) = \overline{M}' + C'$ since \overline{E}' is bounded (Rockafellar [20, Corollary 9.1.1]).

Thus, for all $(r, s) \in T$, we have $\overline{G}(r, s) = \sup_{(\alpha, \beta, \gamma) \in \overline{M}' + C'} (\alpha r + \beta s - \gamma)$. Hence, since \overline{G} is finite on T by definition and since \overline{M}' is compact, it must be that $\overline{G}(r, s) = \sup_{(\alpha, \beta, \gamma) \in \overline{M}'} (\alpha r + \beta s - \gamma) = \max_{(\alpha, \beta, \gamma) \in \overline{M}'} (\alpha r + \beta s - \gamma)$. It follows that $\overline{G}(r, s) = \max_{(\alpha, \beta, \gamma) \in \overline{\Phi}} (\alpha r + \beta s - \gamma)$

¹² Given a set S , $0^+ S$ denotes the recession cone of S , i.e. $0^+ S = \{y: \forall x \in S, \forall \mu > 0, x + \mu y \in S\}$.

¹³ Given a set S , $\text{exp}(S)$ denotes the set of exposed points of S .

¹⁴ Given a real-valued function f , $\text{epi}(f)$ denotes the epigraph of f , i.e. $\text{epi}(f) = \{(x, \gamma): \gamma \geq f(x)\}$.

for all non-empty, compact, and convex set $\bar{\Phi} \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ such that $\bar{M}' \subseteq \bar{\Phi} \subseteq \bar{M}' + C'$. For the converse, first assume that $\bar{\Phi} \not\subseteq \bar{M}' + C'$, i.e. that there exists $(\alpha_0, \beta_0, \gamma_0) \in \bar{\Phi} \setminus (\bar{M}' + C')$. Then, since $\bar{M}' + C'$ is closed and convex and contains no line, there exists $(r, s, t) \in (\mathbb{R}^I)^2 \times \mathbb{R}$ with $t \neq 0$ such that $\alpha_0 r + \beta_0 s + \gamma_0 t > \alpha r + \beta s + \gamma t$ for all $(\alpha, \beta, \gamma) \in \bar{M}' + C'$. Clearly, it must then be that $(r, s, t) \in C'^\circ = T \times \mathbb{R}_-$. Hence, if we let $(r', s') = (\frac{r}{|t|}, \frac{s}{|t|}) \in T$, we have $\alpha_0 r' + \beta_0 s' - \gamma_0 > \alpha r' + \beta s' - \gamma$ for all $(\alpha, \beta, \gamma) \in \bar{M}' + C'$, so $\sup_{(\alpha, \beta, \gamma) \in \bar{\Phi}} (\alpha r' + \beta s' - \gamma) > \sup_{(\alpha, \beta, \gamma) \in \bar{M}' + C'} (\alpha r' + \beta s' - \gamma) = \bar{G}(r', s')$. Now, assume that $\bar{\Phi} \subseteq \bar{M}' + C'$ but $\bar{M}' \not\subseteq \bar{\Phi}$, i.e. that there exists $(\alpha_0, \beta_0, \gamma_0) \in \bar{M}' \setminus \bar{\Phi}$. Then there exists $(\alpha_0, \beta_0, \gamma_0) \in \bar{E}' \setminus \bar{\Phi}$ (Rockafellar [20, Theorem 18.6]) and, hence, there exists $(r, s, t) \in (\mathbb{R}^I)^2 \times \mathbb{R}$ with $t \neq 0$ such that $\alpha_0 r + \beta_0 s + \gamma_0 t > \alpha r + \beta s + \gamma t$ for all $(\alpha, \beta, \gamma) \in \bar{\Phi} + C' \subseteq \bar{M}' + C'$ (Rockafellar [20, Corollary 25.1.2]). Clearly, it must then be that $(r, s, t) \in C'^\circ = T \times \mathbb{R}_-$. Hence, if we let $(r', s') = (\frac{r}{|t|}, \frac{s}{|t|}) \in T$, we have $\alpha_0 r' + \beta_0 s' - \gamma_0 > \alpha r' + \beta s' - \gamma$ for all $(\alpha, \beta, \gamma) \in \bar{\Phi}$, so $\sup_{(\alpha, \beta, \gamma) \in \bar{\Phi}} (\alpha r' + \beta s' - \gamma) < \sup_{(\alpha, \beta, \gamma) \in \bar{M}' + C'} (\alpha r' + \beta s' - \gamma) = \bar{G}(r', s')$. \square

Let $\bar{M}'' = \{(\alpha, \beta, -\gamma) : (\alpha, \beta, \gamma) \in \bar{M}'\}$ and $C'' = C \times \mathbb{R}_-$. By Lemma 12, for all non-empty, compact, and convex set $\bar{\Phi} \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$, $\bar{M}'' \subseteq \bar{\Phi} \subseteq \bar{M}'' + C''$ if and only if, for all $(r, s) \in T$, $\bar{G}(r, s) = \max_{(\alpha, \beta, \gamma) \in \bar{\Phi}} (\alpha r + \beta s + \gamma)$. Hence for all non-empty, compact, and convex set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$, (8) holds if and only if $\text{conv}(\underline{M}' \cup \bar{M}'') \subseteq \Phi \subseteq (\underline{M}' + C') \cap (\bar{M}'' + C'')$.

Lemma 13. $(\underline{M}' + C') \cap (\bar{M}'' + C'') = \text{conv}(\underline{M}' \cup \bar{M}'') + (C \times \{0\})$.

Proof. Since $0 \in C' \cap C''$, we have $\underline{M}' \subseteq \underline{M}' + C'$ and $\bar{M}'' \subseteq \bar{M}'' + C''$. Moreover, $\underline{M}' \subseteq \bar{M}'' + C''$ and $\bar{M}'' \subseteq \underline{M}' + C'$ by Lemma 10. Hence $\text{conv}(\underline{M}' \cup \bar{M}'') \subseteq (\underline{M}' + C') \cap (\bar{M}'' + C'')$ since the set on the right hand side is convex. Hence $\text{conv}(\underline{M}' \cup \bar{M}'') + (C \times \{0\}) \subseteq (\underline{M}' + C') \cap (\bar{M}'' + C'')$ since $(C \times \{0\}) = C' \cap C''$. Conversely, let $v \in (\underline{M}' + C') \cap (\bar{M}'' + C'')$. By definition, there exist $(\underline{\alpha}, \underline{\beta}, \underline{\gamma}) \in \underline{M}'$, $(\bar{\alpha}, \bar{\beta}, \bar{\gamma}) \in \bar{M}''$, $\underline{\eta}, \bar{\eta} \in \mathbb{R}_+^I$, and $\underline{\tau}, \bar{\tau} \in \mathbb{R}_+$ such that

$$v = (\underline{\alpha}, \underline{\beta}, \underline{\gamma}) + (-\underline{\eta}, -\underline{\eta}, \underline{\tau}) = (\bar{\alpha}, \bar{\beta}, \bar{\gamma}) + (-\bar{\eta}, -\bar{\eta}, -\bar{\tau}).$$

Hence, setting $\frac{\bar{\tau}}{\underline{\tau} + \bar{\tau}} = \frac{\underline{\tau}}{\underline{\tau} + \bar{\tau}} = \frac{1}{2}$ in case $\underline{\tau} = \bar{\tau} = 0$, we have

$$\begin{aligned} v &= \frac{\bar{\tau}}{\underline{\tau} + \bar{\tau}} ((\underline{\alpha}, \underline{\beta}, \underline{\gamma}) + (-\underline{\eta}, -\underline{\eta}, \underline{\tau})) + \frac{\underline{\tau}}{\underline{\tau} + \bar{\tau}} ((\bar{\alpha}, \bar{\beta}, \bar{\gamma}) + (-\bar{\eta}, -\bar{\eta}, -\bar{\tau})) \\ &= \left(\frac{\bar{\tau}}{\underline{\tau} + \bar{\tau}} (\underline{\alpha}, \underline{\beta}, \underline{\gamma}) + \frac{\underline{\tau}}{\underline{\tau} + \bar{\tau}} (\bar{\alpha}, \bar{\beta}, \bar{\gamma}) \right) \\ &\quad + \left(-\left(\frac{\bar{\tau}}{\underline{\tau} + \bar{\tau}} \underline{\eta} + \frac{\underline{\tau}}{\underline{\tau} + \bar{\tau}} \bar{\eta} \right), -\left(\frac{\bar{\tau}}{\underline{\tau} + \bar{\tau}} \underline{\eta} + \frac{\underline{\tau}}{\underline{\tau} + \bar{\tau}} \bar{\eta} \right), 0 \right), \end{aligned}$$

so $v \in \text{conv}(\underline{M}' \cup \bar{M}'') + (C \times \{0\})$. \square

Finally, let $\Phi = \text{conv}(\underline{M}' \cup \bar{M}'')$. Then (8) holds, as well as the uniqueness result, by Lemma 13. \square

Proof of Theorem 2. Assume X is a mixture space containing a separated triple of alternatives and \mathcal{D} is an indifference-rich, polygon-rich, and calibration-rich domain. Clearly, if there exists

Please cite this article in press as: E. Danan et al., Aggregating sets of von Neumann–Morgenstern utilities, J. Econ. Theory (2012), <http://dx.doi.org/10.1016/j.jet.2012.12.018>

a non-empty, compact, and convex set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ such that (4) holds then F satisfies Independence of Irrelevant Alternatives and Pareto Indifference. Conversely, assume F satisfies these two axioms. By Lemma 1 and Theorem 1, since \mathcal{D} is indifference-rich and polygon-rich, there then exists a unique non-empty, compact, and convex set $\Phi \subset (\mathbb{R}_+^I)^2 \times \mathbb{R}$ such that (2) and the associated uniqueness result hold. Let F' denote the social welfare function defined by (4) with the same domain \mathcal{D} and the same set Φ of weight-constant vectors. Then F' satisfies Pareto Indifference and Independence of Irrelevant Alternatives and, for all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x \in X$, we have $F((U_i)_{i \in I})(x) = F'((U_i)_{i \in I})(x)$. In order to complete the proof of the theorem (including the uniqueness part), it is sufficient to show that $F = F'$.

Lemma 14. *Let F and F' be two social welfare functions on \mathcal{D} satisfying Pareto Indifference and Independence of Irrelevant Alternatives. If $F((U_i)_{i \in I})(x) = F'((U_i)_{i \in I})(x)$ for all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x \in X$ then $F((U_i)_{i \in I})|_{\{x_1, x_2\}} = F'((U_i)_{i \in I})|_{\{x_1, x_2\}}$ for all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x_1, x_2 \in X$.*

Proof. Assume there exist $(U_i)_{i \in I} \in \mathcal{D}$ and $x_1, x_2 \in X$ such that $F((U_i)_{i \in I})|_{\{x_1, x_2\}} \neq F'((U_i)_{i \in I})|_{\{x_1, x_2\}}$, so (without loss of generality), there exists $u \in F((U_i)_{i \in I})$ such that $u|_{\{x_1, x_2\}} \notin F'((U_i)_{i \in I})|_{\{x_1, x_2\}}$. It is sufficient to find some $(\tilde{U}_i)_{i \in I} \in \mathcal{D}$ and $x \in X$ such that $F((\tilde{U}_i)_{i \in I})(x) \neq F'((\tilde{U}_i)_{i \in I})(x)$.

Since $F'((U_i)_{i \in I})|_{\{x_1, x_2\}}$ is a non-empty, compact, and convex subset of \mathbb{R}^2 , there exists $t \in \mathbb{R}^2$ such that $t_1 + t_2 \neq 0$ and $t_1 u(x_1) + t_2 u(x_2) > t_1 u'(x_1) + t_2 u'(x_2)$ for all $u' \in F'((U_i)_{i \in I})$. Three cases may occur: either $t > 0$, or $t < 0$, or $t_1 > 0$ and $t_2 < 0$ (there is a fourth case, $t_1 < 0$ and $t_2 > 0$, but it can be brought back to the third case by permuting x_1 and x_2). If $t > 0$ then, letting $x = x_1 \frac{t_1}{t_1+t_2} x_2 \in X$, we have $u(x) > u'(x)$ for all $u' \in F'((U_i)_{i \in I})$, so that $F((U_i)_{i \in I})(x) \neq F'((U_i)_{i \in I})(x)$. Similarly, if $t < 0$ then, letting again $x = x_1 \frac{t_1}{t_1+t_2} x_2 \in X$, we have $u(x) < u'(x)$ for all $u' \in F'((U_i)_{i \in I})$, so that $F((U_i)_{i \in I})(x) \neq F'((U_i)_{i \in I})(x)$. Finally, if $t_1 > 0$ and $t_2 < 0$ then two cases may occur: either $t_1 + t_2 > 0$ or $t_1 + t_2 < 0$.

If $t_1 + t_2 > 0$ then, since \mathcal{D} is calibration-rich, there exist $x \in X$ and $(\tilde{U}_i)_{i \in I} \in \mathcal{D}$ such that, for all $i \in I$, $\tilde{U}_i|_{\{x_1, x_2\}} = U_i|_{\{x_1, x_2\}}$ and, for all $\tilde{u}_i \in \tilde{U}_i$, $\tilde{u}_i(x_1) = \tilde{u}_i(x_2(-\frac{t_2}{t_1})x)$. Hence $F((\tilde{U}_i)_{i \in I})|_{\{x_1, x_2\}} = F((U_i)_{i \in I})|_{\{x_1, x_2\}}$ and $F'((\tilde{U}_i)_{i \in I})|_{\{x_1, x_2\}} = F'((U_i)_{i \in I})|_{\{x_1, x_2\}}$ since F and F' satisfy Independence of Irrelevant Alternatives, so there exists $\tilde{u} \in F((\tilde{U}_i)_{i \in I})$ such that $t_1 \tilde{u}(x_1) + t_2 \tilde{u}(x_2) > t_1 \tilde{u}'(x_1) + t_2 \tilde{u}'(x_2)$ for all $\tilde{u}' \in F'((\tilde{U}_i)_{i \in I})$. Moreover, since F and F' satisfy Pareto Indifference, we have $\tilde{u}(x_1) = \tilde{u}(x_2(-\frac{t_2}{t_1})x) = -\frac{t_2}{t_1} \tilde{u}(x_2) + \frac{t_1+t_2}{t_1} \tilde{u}(x)$ for all $\tilde{u} \in F((\tilde{U}_i)_{i \in I})$ and $\tilde{u}'(x_1) = \tilde{u}'(x_2(-\frac{t_2}{t_1})x) = -\frac{t_2}{t_1} \tilde{u}'(x_2) + \frac{t_1+t_2}{t_1} \tilde{u}'(x)$ for all $\tilde{u}' \in F'((\tilde{U}_i)_{i \in I})$. Hence the above inequality is equivalent to $\tilde{u}(x) > \tilde{u}'(x)$ for all $\tilde{u}' \in F'((\tilde{U}_i)_{i \in I})$, so that $F((\tilde{U}_i)_{i \in I})(x) \neq F'((\tilde{U}_i)_{i \in I})(x)$.

Similarly, if $t_1 + t_2 < 0$ then, since \mathcal{D} is calibration-rich, there exist $x \in X$ and $(\tilde{U}_i)_{i \in I} \in \mathcal{D}$ such that, for all $i \in I$, $\tilde{U}_i|_{\{x_1, x_2\}} = U_i|_{\{x_1, x_2\}}$ and, for all $\tilde{u}_i \in \tilde{U}_i$, $\tilde{u}_i(x_2) = \tilde{u}_i(x_1(-\frac{t_2}{t_1})x)$. Hence $F((\tilde{U}_i)_{i \in I})|_{\{x_1, x_2\}} = F((U_i)_{i \in I})|_{\{x_1, x_2\}}$ and $F'((\tilde{U}_i)_{i \in I})|_{\{x_1, x_2\}} = F'((U_i)_{i \in I})|_{\{x_1, x_2\}}$ since F and F' satisfy Independence of Irrelevant Alternatives, so there exists $\tilde{u} \in F((\tilde{U}_i)_{i \in I})$ such that $t_1 \tilde{u}(x_1) + t_2 \tilde{u}(x_2) > t_1 \tilde{u}'(x_1) + t_2 \tilde{u}'(x_2)$ for all $\tilde{u}' \in F'((\tilde{U}_i)_{i \in I})$. Moreover, since F and F' satisfy Pareto Indifference, we have $\tilde{u}(x_2) = \tilde{u}(x_1(-\frac{t_2}{t_1})x) = -\frac{t_2}{t_1} \tilde{u}(x_1) + \frac{t_1+t_2}{t_2} \tilde{u}(x)$ for all $\tilde{u} \in F((\tilde{U}_i)_{i \in I})$ and $\tilde{u}'(x_2) = \tilde{u}'(x_1(-\frac{t_2}{t_1})x) = -\frac{t_2}{t_1} \tilde{u}'(x_1) + \frac{t_1+t_2}{t_2} \tilde{u}'(x)$ for all $\tilde{u}' \in F'((\tilde{U}_i)_{i \in I})$. Hence the above inequality is equivalent to $\tilde{u}(x) < \tilde{u}'(x)$ for all $\tilde{u}' \in F'((\tilde{U}_i)_{i \in I})$, so that $F((\tilde{U}_i)_{i \in I})(x) \neq F'((\tilde{U}_i)_{i \in I})(x)$. \square

Lemma 15. Let $U, U' \in \mathcal{P}$, let $n \in \mathbb{N}$, $n > 2$, and let $y_1, \dots, y_n \in X$. If $U|_{\{x,x'\}} = U'|_{\{x,x'\}}$ for all $x = y_1\lambda_1(\dots(y_{n-1}\lambda_{n-1}y_n)) \in X$ and $x' = y_1\lambda'_1(\dots(y_{n-1}\lambda'_{n-1}y_n)) \in X$, $\lambda_1, \lambda'_1, \dots, \lambda_{n-1}, \lambda'_{n-1} \in [0, 1]$, then $U|_{\{y_1, \dots, y_n\}} = U'|_{\{y_1, \dots, y_n\}}$.

Proof. Assume $U|_{\{y_1, \dots, y_n\}} \neq U'|_{\{y_1, \dots, y_n\}}$, so (without loss of generality), there exists $u \in U$ such that $u|_{\{y_1, \dots, y_n\}} \notin U'|_{\{y_1, \dots, y_n\}}$. It suffices to find some $x = y_1\lambda_1(\dots(y_{n-1}\lambda_{n-1}y_n)) \in X$ and $x' = y_1\lambda'_1(\dots(y_{n-1}\lambda'_{n-1}y_n)) \in X$, $\lambda_1, \lambda'_1, \dots, \lambda_{n-1}, \lambda'_{n-1} \in [0, 1]$, such that $u|_{\{x,x'\}} \notin U'|_{\{x,x'\}}$.

Since $U'|_{\{x,x'\}}$ is a non-empty, compact, and convex subset of \mathbb{R}^n , there exists $t \in \mathbb{R}^n$ such that $t_1, \dots, t_n \neq 0$ and $t_1u(y_1) + \dots + t_nu(y_n) > t_1u'(y_1) + \dots + t_nu'(y_n)$ for all $u' \in U'$. Three cases may occur: either $t > 0$, or $t < 0$, or neither $t > 0$ nor $t < 0$. If $t > 0$ then, letting $x = x' = y_1\frac{t_1}{t_1+\dots+t_n}(\dots(y_{n-1}\frac{t_{n-1}}{t_{n-1}+t_n}y_n)) \in X$, we have $u(x) = u(x') > u'(x) = u'(x')$ for all $u' \in U'$, so that $u|_{\{x,x'\}} \notin U'|_{\{x,x'\}}$. Similarly, if $t < 0$ then, letting $x = x' = y_1\frac{t_1}{t_1+\dots+t_n}(\dots(y_{n-1}\frac{t_{n-1}}{t_{n-1}+t_n}y_n)) \in X$, we have $u(x) = u(x') < u'(x) = u'(x')$ for all $u' \in U'$, so that $u|_{\{x,x'\}} \notin U'|_{\{x,x'\}}$. Finally, if neither $t > 0$ nor $t < 0$ then, permuting x_1, \dots, x_n if necessary, we have $t_1, \dots, t_k > 0$ and $t_{k+1}, \dots, t_n < 0$ for some integer k , $1 < k < n$. Since $t_1u(y_1) + \dots + t_nu(y_n) > t_1u'(y_1) + \dots + t_nu'(y_n)$ for all $u' \in U'$, there exists no $u' \in U'$ such that $t_1u(y_1) + \dots + t_ku(y_k) = t_1u'(y_1) + \dots + t_ku'(y_k)$ and $t_{k+1}u(y_{k+1}) + \dots + t_nu(y_n) = t_{k+1}u'(y_{k+1}) + \dots + t_nu'(y_n)$. Hence, letting $x = y_1\frac{t_1}{t_1+\dots+t_k}(\dots(y_{k-1}\frac{t_{k-1}}{t_{k-1}+t_k}y_k)) \in X$ and $x' = y_{k+1}\frac{t_{k+1}}{t_{k+1}+\dots+t_n}(\dots(y_{n-1}\frac{t_{n-1}}{t_{n-1}+t_n}y_n)) \in X$, there exists no $u' \in U'$ such that $u(x) = u'(x)$ and $u(x') = u'(x')$, so that $u|_{\{x,x'\}} \notin U'|_{\{x,x'\}}$. \square

Lemma 16. Let U and U' be compact subsets of \mathbb{R}^X . If $U|_Y = U'|_Y$ for all finite subset Y of X then $U = U'$.

Proof. Assume $U \neq U'$, so (without loss of generality) there exists $u \in U \setminus U'$. It is sufficient to find some finite subset Y of X such that $u|_Y \notin U'|_Y$. By definition of the product topology, since $u \in \mathbb{R}^X \setminus U'$, which is an open set since U' is closed, there must exist a finite subset Y of X and a collection $(O_y)_{y \in Y}$ of open subsets of \mathbb{R} such that $u \in O \subseteq \mathbb{R}^X \setminus U'$, where $O = (\prod_{y \in Y} O_y) \times \mathbb{R}^{X \setminus Y}$. By definition of O , it follows that $u|_Y \notin U'|_Y$. \square

By Lemma 14, we have $F((U_i)_{i \in I})|_{\{x_1, x_2\}} = F'((U_i)_{i \in I})|_{\{x_1, x_2\}}$ for all $(U_i)_{i \in I} \in \mathcal{D}$ and all $x_1, x_2 \in X$. Hence, by Lemma 15, we have $F((U_i)_{i \in I})|_Y = F'((U_i)_{i \in I})|_Y$ for all $(U_i)_{i \in I} \in \mathcal{D}$ and all finite subset Y of X . Hence, by Lemma 16, we have $F((U_i)_{i \in I}) = F'((U_i)_{i \in I})$ for all $(U_i)_{i \in I} \in \mathcal{D}$, so $F = F'$. \square
